Source record: 97450

Try the "Field Day Special" instead. Go to http://www.eznec.com/miscpage.htm for the software for designing one. They can be easily made to rvs the pattern with the flick of a switch.

The "Field Day Special" Antenna

The Field Day Special is a two-element wire beam with a unidirectional pattern. It's similar to the "ZL" special, except that its elements are the same length. This makes it easy to reverse the pattern by using two feedlines, one at the center of each element. The original antenna was described in June 1984 QST. An antenna like this can't directly be scaled for other bands unless the size of the twinlead it's made from is scaled in proportion. However, using the program available here, you can design your own for the frequency band of interest. By changing the various dimensions, you can trade gain/beamwidth, feedpoint impedance, and bandwidth. Improvements in the program have been made since the article was published, so an optimal design for 20 meters will have dimensions slightly different than the ones shown in the article. The currents in the elements of one design were measured and found to agree very closely with those predicted by the program. Quite a number of these have been built by various people for several bands, with universal reports of operation as predicted. I use a 20 meter version nearly every year for Field Day, and occasionally 15 and 40 meter versions as well. 20 and 15 meter Field Day Specials have been my primary home QTH antennas for these bands for a number of years. Download FDSP~.EXE, then follow the directions under "Downloadable Files", above. More information about the antenna, including construction and feeding, is included in one of the expanded files. The program is a DOS program and can be run from the Windows 95/98/NT DOS prompt.

2. Lightning Protection

Newsgroup: rec.radio.amateur.antenna
Date: 2004-04-01 01:13:24 UTC
From: Joseph Fenn <jfenn@lava.net>
Message-ID: <Pine.BSI.4.58.0403311455400.17603@malasada.lava.net>
Source record: 97451

Well what I do is remove the HF coax line when thungder and lightning
is approaching. In the shack I have a mounting box with a normal
coax connector where I attach the ant feed to the xmtr.
I made a little device useing a new Coax plug which has a 2k resistor
connected to its center connector. This 5 watt resistor is then
connected to a 1/4 watt neon bulb which is in turn connected to the
gnd side of the connector. As a storm approaches, I glance at
it once every 5 mins or so and if If see the neon bulb flashes
due to static buildup on the feed line from the antenna, I keep my
eye on it. If it startes flashing about every 15 seconds or even
every 5 seconds, I get the hell out of the shack. This system
was used on many varieties of commercial radio systems as well as
in Military rcvr front ends where even small amounts of static
buildup could ruin the front end of a sensitive receiver.
Particularly on VHF freqs this often occurred. No amount of
grounding of your Ant is going to totally prevent damage from
a direct lightning strike on your metal mast or tower.
Lightning can strike either a tower and or feedline and then arc
accross to the structure such as your house or ham shack. That
type of strike can even split a concrete house wall right down
the middle. We had a person here a couple of months ago that
got struck by lightning but not directly. The bolt hit a power
line then arced from it down to the person it struck. That
person survived. In fact he was hospitalized just to check
him out and no permanent physical damage occurred to the
guy!

That's simply a false statement. So please tell us what objection do
you have to the graphs in the ARRL Antenna Book (a previous reference
of mine) from which everything I have said logically follows.

> I believe Tom's point was that more information was known or available
> preceding the "approximation" than following it, which portrays the
> "approximation" as a degradation of knowledge.

That's a laugh since most hams are incapable of measuring anything
like 3000+j2000 ohms. I have no idea what your (or Tom's) agenda is
but it is apparently to convince everyone that shortcuts are useless
and only gurus like yourself can bestow the sacred cow knowledge of
antennas on us, the unwashed masses.

> get to your equipment thru your gnd system?

I guess opinions will vary on this, but I am never connected to my outside ground. Don't use a shack ground connection anymore. But if I still did, yes, I would unhook it during storms. It's ok to have the ground, if properly set up, IE: "star config" to the ground window, but I prefer to be totally isolated from everything outside. I ground my feedlines outside, and thats it. All thats left is unplugging the gear if I think it's bad enough. And I really don't have to do that. Just makes me feel better...MK

7. Help retuning 2 meter Diamond f22a to aircraft band, please

Newsgroup: rec.radio.amateur.antenna
Date: 2004-04-01 06:53:40 UTC
From: joe <joe@nospam.com>
Message-ID: <eKWdnXpb1I6VIfbdRVn_iw@comcast.com>
Source record: 97456

I recently picked up a Diamond f22a 2 meter antenna. I would like to tune it to the aircraft band (123mhz). I have a couple of questions: How much length would I need to add to it? It looks like I can add about 8-10" inside the top fiberglass tube. Is it worth the trouble? Will it improve reception. I've done google searches and even talked to Diamond and can't come up with a figure. Any help would be greatly appreciated.

Joe

> Antenna modeling for "listening only" is probably overkill but try the EZNEC

For a beginner, without having to bother about segments- and
tag-numbers and counts, you could try 4nec2 freeware program.
In this there is a drag- and draw style sub-program included which you
could use to 'draw' your antenne instead of specifying separate wire,
excitation, loading and/or ground records.

However, see for yourself.

Arie.

Once again: The ARRL Antenna Book, 15th edition, page 2-10, the graph of resistance Vs reactance in Fig. 10 for frequencies from f/2 to 2f. The same graph appears as a series of graphs in the ARRL Antenna Book CD, ver. 2.0. Everything I said falls out directly from those graphs.

Fig. 10 is for a 1/4WL monopole so it has to be extrapolated for a 1/2WL dipole. The point of maximum reactance is approximately equal to the (anti)resonant resistance divided by 2. The resistance at the point of maximum reactance is approximately equal to the (anti) resonant resistance divided by 2.

How can you guys get so upset at someone who simply describes a graph in the ARRL Antenna Book?

So? What's wrong with that? Cecil is also a fine Texas ham
who prods many of us into gaining a deeper knowledge of antennas
and transmission lines by challenging our closely held assumptions
and making us think more deeply about things we thought we knew.
Reg does the same thing, but less tenaciously. As irritating as these
gentlemen can be, they perform a valuable function on this newsgroup.
You have to goad the ox before it'll move.

Source record: 97371

You should be able to find graphs of the radiation pattern versus element length in many antenna books. 5/8 wave is the longest you can make a single element and maintain a single lobe. Beyond that, the pattern splits into two (and more, when the element is even longer) lobes. To maintain a single lobe (a "flat pancake" pattern) with a longer antenna, you need a way to divide the antenna into multiple elements, and have the current in them all in-phase. You can simulate a ground-plane antenna in programs like EZNec, and if you just look at a vertical monopole over ground, or a center-fed dipole in freespace that's twice as long, you should be able to use the free evaluation version of EZNec. I'm not sure if the free version allows enough wires/segments to do a ground plane with radials, but possibly. See www.eznec.com.

Cheers,
Tom

22. Tuning a Discone and SWR's

Newsgroup: rec.radio.amateur.antenna
Date: 2004-04-01 16:58:42 UTC
From: Macman <golf4pints@hotmail.com>
Message-ID: <lv-dndUpU_Oi1_HdRVn-gw@comcast.com>
Source record: 97372

My SWR's are basically flat on the lower end of the 2m scale, but there is a significant jump starting at 146.000 thru 147.999. Starting at 147.000, it's pushing the 3:1 threshold and going over the 3:1 threshold the higher in the freq band I go.

I have a discone antenna and would like some suggestions as to tuning methods. From what I know, if the SWR's are high on the 'top' end of the range, the main vertical whip needs to be trimmed.

Does that sound right or is there something else I need to check on first?

Thanks.

Al, WA4GKQ wrote:
"---as frequency is increased past quarter-wave resonance, I`ve noticed with interest that both reactance and resistance peak at different times, as they increase with frequency toward the half-wave point."

At the end of the ARRL Antenna Book edoition 19 chapter on Antenna Fundamentals is a bibliography which includes P.H. Lee`s "The Amateur Radio Vertical Antenna Handbook". In my 1974 edition, there are Figs. 18(A) Vertical Antenna Base Resistance and 18(B) Base Reactance, versus height in wavelengths.

Figs. 18(A) and (B) clearly show the variation of R and X just short of 1/2-wavelength and their dependence on the characteristic impedance of the antenna.

If the "Antenna Book" doesn`t have the information, one of the bibliography books most lilkely does.

Best regards, Richard Harrison, KB5WZI

Hi OM,

There is no "tuning" of Discones. They are what they are,
broadbanded. Their lower frequency of use is basically defined by the
length of the lower skirt elements (verging on quarterwave). The
higher frequency is more a function of the feedpoint gap between the
disc and the cone. If this is adjustable, you are in luck. If it is
not adjustable, something else is broke.

As you describe a vertical whip, that is NOT the usual part of a
Discone, but is a means to offer an even lower single band's coverage,
usually 6M. It's addition is not a bonus at higher frequencies (and
may actually make the antenna deaf). However, this has nothing to do
with SWR. If this is a 6M addition, and you have the option of
removing it entirely, try that.

For reasonable approximations with the free demo, just skip the
radials and use the mininec ground option.

Well, since you deleted my reference, we can assume your intent is
unethical, uncivil, and irrational.

It's essentially a no-brainer, Richard. The resonant feedpoint impedance
for a 1/2WL resonant dipole is around 60 ohms. The anti-resonant resonant
feedpoint impedance for a one-wavelength dipole is around 6000 ohms.
Between those two values of frequency, the reactance goes from zero, peaks,
and goes back to zero. How you can argue with that is beyond belief. All
this is clearly shown in my references that you deleted. Why are you afraid
to face the facts?

Thank you Richard. This my first discone I've had a chance to play with and didn't realize that verticle 'whip' was 6m. The lower radiating elements that make up the cone; two of them have telescoping elements inside of the main element. Maybe some gentle adjustments there would improve the top end of the 2m band.
Thanks for you input.

Hi OM,

That determination of 6M was by dint of simple guess work. The
dimensions compared to wave length (quarterwave) will bear out what
part is responsible for the lowest frequency. The inclusion of
telescoping elements further complicates the analysis. Perhaps if you
were to supply dimensions, then we could shake the characteristics
out.

Hi Dan,

Been a long time since I've heard anyone described as totally tubular,
much less simple tubes....

Anyway, RF current is pretty much confined to the outermost layer of
metal for any conductor (re: skin effect). On the basis of weight and
cost reduction, there is no merit in using solid rods when you move on
out of the common wire dimensions. In other words, the missing metal
hardly contributed to lower resistance for RF.

Uhhhhh Richard, Those graphs in the ARRL Antenna Book are the
ORIGIN of my approximation. Exactly what is it about those
graphs that you disagree with? It is obvious from viewing
the graphs that the maximum reactance is about 1/2 of the
maximum resistance. It is also obvious that the resistance
at the maximum reactance point is about 1/2 of the maximum
resistance. That's exactly what my approximation said.

I've got one rolled up in my shack -- used to use it but went to other
things after a while. The performance was not bad, but making one that
is strong enough to span any distance is difficult. I had to run a piece
of nylone cord through the dielectric, threaded in and out.

Another chum, now a sient key, used one for years and seemed happy with
it.

The spelling is Lattin, and you can find it on the net through Google.

Hi Richard,

Just wanted to mention, there are several discones on the market assembled with circular arrays of horizontal and 45-degree angle groundplanes plus a trimmable vertical element which is the only radiating element of those discones. The vertical radiating element comes from the factory cut to 2m but can be shortened to suit. I have owned a few and they are anything but deaf.

Best regards,

Source record: 97394

Quite a few years ago, there were a couple of articles -- in Ham Radio magazine, I believe --, which addressed that topic. As I recall, the author used an optimization program that allowed the shape to vary. He ended up with elements bent kind of like a gull wing, and considerably longer than a half wavelength -- more like a wavelength if I recall correctly. The gain was substantially more than for a Yagi, but I don't remember how good the F/B ratio was. I believe he did construct and measure some actual antennas.

I'm sorry I don't recall the name of either the author or the articles. Hopefully, though, this posting will spur someone with a better memory (and that includes just about everyone) to recall and report enough information for you to find the articles.

The articles were very interesting, but it looked to me like the construction problems would outweigh the benefits. Apparently I'm not the only one to reach that conclusion, because in the intervening years I've never seen an actual antenna resembling that design.

Hi OM,

Well, it is a bit difficult to count the number of radial elements,
but it looks like between 6 and 8. Also, given that it operates from
25MHz (in an attempt to encompass the earth, sea, and sky) it must
ultimately disappoint you somewhere. That somewhere is that above 3
to 4 times the lowest frequency, those higher frequencies invest their
attention to sending/getting signals from overhead instead of out and
away towards the horizon. Also with fewer radial elements, there are
going to be gaps in SWR coverage (your reports confirm this).

Too often the Discone vendor is content to cite only the matching
characteristics and not mention that directionality explodes upward
like a wind swept umbrella. So, even if it did match to 2M, it would
tend to be deaf. Like I said, try to eliminate the top whip, and
retract the lower skirts lengths to roughly 1M length or less.

Hi Jack,

It would be if it were designed to a lowest resonation (through
lengths involved) at 25MHz.

Richard,

That makes sense...and the reason the ones designed as "scanner" antennas are usually much shorter radials too, about 30" I think.. Though they advertise 25-1300 mhz, I only used them for the 118-139 and 225-400 mhz aircraft bands and 156 mhz marine band (where it was a poor performer in rx and tx). The newer concept of discone called the "Scantenna" although for Rx only, is a vastly superior performer than the standard discone design in the bands I mentioned.

I currently use a J-Pole for marine band and have good 2-way between CG Groups and aircraft over 100 miles distant. Accordingly, a J-pole woould seem to be a natural for 2m work since mine is so close to that at 156.8 mhz, and it outperforms fishing-pole makers that advertise upwards of 6dbi.

I think you're referring to the Landstorfer-Sacher Yagi design?

http://www.cebik.com/eb.html has some information on these. It's
something akin to an EDZ (extended double zepp) beam. A 2-meter
3-element L-S Yagi shows gain in the 9.7 dB range, with F/B ratios of
16-23.

Interesting design. Not the easiest thing in the world to construct,
I suspect.

51. Doppler RDF Antennas

Newsgroup: rec.radio.amateur.antenna
Date: 2004-04-02 05:27:14 UTC
From: George <look@signature_to.reply>
Message-ID: <SQ6bc.11380$Dv2.2937@newsread2.news.pas.earthlink.net>
Source record: 97402

Is anyone familiar with three-element quarter-wave or half-wave (Adcock) Doppler antennas for RDF applications? These antennas are most commonly seen as four-element designs, but I'd like to build a three-element version that trades off directional accuracy for smaller size. I've come across articles on the Web stating that they *SHOULD* work, but I haven't found a reference to one that has actually been built.

Thanks in advance.

George K6GW

59. Sources for Inexpensive RG-8??

Newsgroup: rec.radio.amateur.antenna
Date: 2004-04-02 15:38:00 UTC

I'll have some fairly long runs of coax to HF antennas (21Mhz max) to Field Day antennas. One of the antennas will be an 80M G5RV with their usual nasty SWRs so a foam-type cable is indicated. Since it's a very temporary non-critical installation I'm not about to spend premium bucks on 9913 or any of it's relatives like I do for the home station. A non-contaminating jacket would be nice but is not much of an issue. Does anybody have any suggestions about vendors who are selling foam RG-8 for lower-than-usual prices?

Thanks, Brian w3rv

Could you get hold of 75 ohm cable instead? G5RV recommended it for this
antenna anyway and regardless of what you use you will need a tuner.
RG 59 may be cheaper and CATV cable may be free or someone may have enough
to help you out.

Hi Brian, what bands will the G5RV be used on? Only 80m?
The SWR is not all that nasty on 80m being about 20:1
on the ladder-line and 2:1 on the coax.

Here's one of my rules-of-thumb for which I am infamous. :-)

Given a 102 ft. Dipole at 40 ft. fed with 450 ohm ladder-line
and used on 3.8 MHz, for a ladder-line length between about
25 ft. and 100 ft., the resistance looking into the ladder-line
is about equal to the length of the ladder-line. Thus for 25 ft.
of ladder-line, the impedance looking into the ladder-line is
about 25+jXL1. For a ladder-line length of 50 ft., the impedance
looking into the ladder-line is about 50+jXL2. For a ladder-line
length of 100 ft., the impedance looking into the ladder-line
is about 100+jXL3. Does that give you any hints on how to match it?

According to EZNEC, the impedance looking into 50 ft. of ladder-line
is about 50+j466. Use two series 180pf caps to neutralize the inductive
reactance and you have a feedpoint impedance of 50 ohms. A dual ganged
300pf variable would be ideal.

A 102 ft dipole 40 feet in the air fed with 50 ft of ladder-line
tuned with a dual-gang variable cap on the antenna side of a balun/
choke and no tuner box. Doesn't that sound like a perfect 75m field
day antenna?

Weird! They show up fine on my Linux workstation using Mozilla 1.5
and on my laptop using Mozilla Firefox 0.8. I saved on of the images
to disk, and it proved to be a very ordinary GIF file, with only two
colors. They ought to be visible in any standard browser.

I contacted LB about the problem, and he said he'd received reports
similar to mine. He's contacted the web host but hasn't heard back yet.
So it's being addressed.

My browsers are both standard as far as I can determine. My firewall is
set to a pretty touchy level, though, so that might be the cause. But I
haven't had trouble with pictures at other sites.

I misspoke above. "100 ft." should have been "50 ft."

> For a ladder-line
> length of 100 ft., the impedance looking into the ladder-line
> is about 100+jXL3.

It is true that the resistance for 100 ft. of ladder-line is about
100 ohms, but it is 100-jXC, not 100+jXL. Sorry for the faulty memory.

67. Re: EZNEX Modeling Question

Newsgroup: rec.radio.amateur.antenna
Date: 2004-04-02 21:50:31 UTC
From: noexqs <PE2WDO@noexqs.demon.nl>
Message-ID: <106rnnon7emun8d@corp.supernews.com>
Source record: 97418

I've modelled a 8 element VHF loop-yagi by describing it into an excel
spreadsheet. I suppose you could do the same for helix type of antenna.
Except that you use an additional Z-axis. I'm not very familiar
with this particular antenna but modelling it shouldn't be so hard.

Therefore, this is what I did with my loop-yagi:
I divided the circumpherence of a loop into 24 parts (of 15 degrees).
Described end-points (x,y) = r*cos(a), r*sin(a) (r-radius, a-angle)
Added a Z value for each subsequent loop.
Modelled into the desired format and exported the output to a datafile
and then imported the results into the modelling software.

After optimizing in the modelling software, I exported the
calculated results and used another
spreadsheet to recover the actual length of the loops, simply by
adding the lenght of the 24 parts of each loop (using basic math).
After verification in a few modelling programs I
then built a prototype 70cm/435Mhz loop-yagi with plain electric
"house-wire"
to validate the calculations. The modelling proved quite accurate.

The endresult now is a 8 element 144Mhz loop-yagi (2WL boom) which gives
about 12.4dBd gain, about 22dB F/B and good pattern for DX
and SAT-work. Another advantage that this antenna
has a very robust construction and by making the radiating
element to rotate, you only need one-and-the-same antenna, no special
feeds for whatever polarisation. This gives amazing results!

Hope this helps.
Suc6 with the job.

Since you'll probably be working FM, assumably repeaters, it doesn't matter. Either will work just fine. It's the actual antenna that you need to be concerned about.

I hope you are successful in making people think so. :/ It'll be easier pickings for me and my superior, lower overall loss, radiating device. :) I already use the *perfect* 75m field day antenna. It's a regular old full size coax fed dipole. Why would anyone want to clutter up low loss perfection? Boggles my mind...:/ But it's ok, like I said, it's to my advantage on that bug infested night in June. I hope everyone else is using G5RV's, windoms, isotrons, EH's and other such things.. Makes it easier for us. .:) MK

When using one of those external, mag-mount antennas that plug into the antenna jack just below the stubby antenna of a flip phone, it is better to remove the stubby antenna?

On receive, I would think it makes little difference. On transmit, however, if the stubby antenna is not removed, won't energy be wasted on in-vehichle propagation that would be better directed to the mag mount on the roof?

yes, the basic design is bidirectional. it has been a while since I played
with it, but I think you could design it for one frequency and get a
cardioid pattern by spacing the antennas 1/4 wave apart and using feedlines
that are 1/4 wave longer to one than the other.

The NMO is easier to mount in a blind hole; you need only be able to fish
the coax.
It also presents a lower profile when the antenna's removed.
NMO is my choice when you drill a hole in sheet metal.
Electrical performance is a wash.

Hi Dave,

For any of a couple of reasons, principal among them being simplicity.
I have 2M, 220 and 440 versions with drooping radials that match quite
easily and couldn't be any cheaper for only the cost of the SO239. As
for "it's large vertical lobe," I am not sure what you mean by that.
The 5/8ths has more gain, but not so much more in a band and
application that is dominated by line of sight communication. If the
difference between the two is important to getting into a repeater,
getting into the repeater is not the same as full quieting and can be
an obnoxious advantage suffered by those who have to listen to a poor
connection. Such problems are more simply remedied by elevating the
existing antenna than trying to "add gain."

Hi Ken,

Do you have the option to removing it? If so, goferit.

If not, then the jack must disconnect it when you insert your external antenna (VCR/DVD products have such switching jacks that look no different than conventional RCA bulkhead connections). If this option does not exist, then the manufacturer must consider their paralleling of having no negative consequence in efficiency (which is recovered and supplemented in the better external antenna situation). However, this last is simply a guess that can be borne out only through your experience.

I suspect the above antenna is more efficient than your coax-fed dipole.
There's negligible loss in the 50 ft. of ladder-line and negligible loss
in the series caps. No tuner required, therefore no lossy coil. So where's
the loss? Please be specific and provide data to back it up.

The latest evil virus spreading trick has been to put the dangerous
file extensions inside a ZIP file.

Anyone who runs an executable file from an unknown source is real
close to asking to have their system trashed.

Although, the original message is true. Running that file would stop
you from worrying about your current problems.

Also, I understand that many cell phone antennas also use the NMO.
This might turn a negative into a positive when reselling the car.

Source record: 97342

Dan Jacobson wrote:
"Just curious, what is the result of computer modeling for the ideal shape of Yagi elements?"

Advantage of a Yagi is gain in a small space due to close element spacing. This also results in lower radiation resistance as the size goes down with increased coupling and gain. To get a more convenient Yagi drivepoint impedance (5 ohms is not usually convenient), a folded dipole is often used as the driven element. That can multiply the impedance by 4. See "Multi-Element V-H-F Beam Antennas" section of Editors and Engineers "The Radio Handbook", William I. Orr, W6SAI, Editor 15th Edition.

The tapered elements, large at the boom and small at the tip as shown in the "ARRL Antenna Book", are mechanically sound but the taper is the reverse of that needed for wide bandwidth.

Cones which grow in size from feedpoint to open ends have an advantage of more uniform characteristic impedance.

Kraus says on page 229 of his 1950 edition:
"Whereas the characteristic impedance of a biconical antenna is uniform, the impedance of antennas of shapes other than conical is nonuniform."

Terman says on page 921 of his 1955 edition:
"A particularly effective manner of utilizing the thick antenna principle to obtain a wideband is to employ a cone antenna. Excitation at the apex starts a spherical wave, as illustrated in Fig. 23-56, which spreads out along the cone and in adjacent space without reflection until reaching the end of the cone."

I don`t know what a computer program indicates as an ideal shape for a Yagi`s driven element. The conical element shape may be a candidate for computer optimization. Kraus and Terman have suggestions about the apex angle and length of the cone.

Best regards, Richard Harrison, KB5WZI

Hi to you all !

I have this question of which I am curious what you think of it.

In my situation it's about shortwave listening, not transmitting.

I have understood that it's a good idea to put a HF choke directly
under the feedpoint of an antenna (mine is a T2FD with balun) to
filter noise etc from PC's, TV, from the signal.
Also ferrite in the coax line should decrease the noises.

I was wondering it, besides the filtering of unwanted products, also
WANTED signals are being attenuated. So is the signal weakened as
well?

I myself have 7 turns through 2 ferrite cores under the feedpoint of
the T2FD.
All works ok to me, but I was just wondering......

So is the weapon worse than the thread ??

And is it for transmitting only or also applicable for listening
situation?

Thanks for your time!

Hi Richard,

This analysis is derived from Schelkunoff's work that was later (1952)
offered in his "Advanced Antenna Theory." This material is offered in
a more accessible form in "Antennas and Radiowave Propagation," Robert
E. Collin, 1985 with the following observation:
"In his book Schelkunoff shows .... the biconical antenna theory
provides a theoretical basis for assuming a sinusoidal current
distribution on thin-wire antennas."

Basically, the biconical antenna theory is the basis for the
fundamental treatment of antenna as a non-terminated transmission line
by which all thin-wire antennas may be shown to devolve from (as the
degenerate forms of infinitely small radius cone sections). Such
treatment allows those interested to observe both the SWR relationship
(E/I distribution) of thin-wire elements compared to what you
correctly identify as the uniform impedance of the large cone angle
forms and both be mathematically consistent with such diverging
characteristics (which is to say those who oppose the discussion of
Antenna as transmission line are unaware of this work).

However, as to its application in a Yagi-Uda design, it has to be
particularly unrewarding as nearby elements preclude a full-blown
conic development without the attending physical interference.

Hi Bob, Irv,

Over the past couple days I've done some investigation with this
design and it has as many dead-ends as any "revolutionary" idea that
has been revealed here by breathless inventors.

For one, there are any number of hits in the search engines for the
Lattin (W4JRW) antenna. However, without exception they all reference
the same pdf file. Examination of this file does not do the inventor
justice through the omission of William J. Lattin's name (aside from
what would be due to the presumption of the antenna's name which along
the way has been corrupted). I only found his full name through Irv's
earlier (2002) posting here (W4JRW has been re-assigned as a vanity
call). Any attempt to confirm the presumed patent (1960) is
frustrated by the lack of its number (required for a patent search,
name searches are limited to post 1976).

However, when I attempted to analyze the design in EZNEC, it showed
nothing near the presumed bands without extensive trimming (albeit,
the suggest foam twin lead suggested by that single pdf reference is
not amenable to EZNEC analysis, and I simply used ladder line). Even
then, the various "traps" are neither intuitively designed nor
correctly driven. Hence with only one design extant, and the reports
of difficulty in tuning it up (not withstanding Irv's suggestions),

and confounding results from modeling; it then seems suspect on the face of it. The "theory" offered is tantalizing, but I see so many problems, that such "theory" appears to be more the result of a fantasy with numbers than the actual proof of the design/test/data cycle.

Let's face it, if the design were serviceable, it would be more current given 44 years of exposure.

Richard Clark wrote:
"This analysis is derived from Schelkunoff`s work that was later (1952) offered in his "Advanced Antenna Theory"."

Kraus acknowledges this at the beginning of his 1950 "Antennas" chapter 8:
"This problem (input resistance and reactance) is most simply approached by Schelkunoff`s treatment of the biconical antenna (S.A. Schelkunoff, "Electromagnetic Waves"1943) which will be outlined in the following sections."

As Reg Edwards says, these guys all copied each other`s work. But, they nearly always gave each other the credit due.

Other than a few discones, which have 180-degrees as one of their vertex angles, I don`t see many amateur conical antennas despite the obsession with bandwidth and SWR. Skeletal designs might retain desirable characteristics without extreme cost and complexity.....Nah, the plain thin wire dipole is too simple and easy.

Best regards, Richard Harrison, KB5WZI

Funny, it's made a significant difference for me in the decade or so I've
been using them.

A folded monopole is almost as simple, and has more gain as well.

?? More gain is worse?
I don't follow you. Being able to run into the same machines at lower power
is always good for my batteries, and taking me from noisy to quiet on the
same power is always a good thing.

> Such problems are more simply remedied by elevating the
> existing antenna than trying to "add gain."

Altitude is king, as long as you don't throw it all away in the feedline.

Less than 1 dB is significant? Are we talking about VHF FM DXing?

>> If the

>?? More gain is worse?

More gain is not always enough gain. Again, if this is about getting
into a repeater, the less than 1dB difference that holds it open with
a scratchy signal is no panacea. There is nothing your contacts can
do to improve your poor S/N ratio; so, in a sense, it being better is
only from your point of view and an imposition on others to strain
their ears.

>I don't follow you. Being able to run into the same machines at lower power
>is always good for my batteries, and taking me from noisy to quiet on the

The same logic applies to getting your buddies to push your car to
boost your MPG. Better MPG cannot be said to be bad, but then you
aren't the one doing the pushing.

>> Such problems are more simply remedied by elevating the
>> existing antenna than trying to "add gain."
>
>Altitude is king, as long as you don't throw it all away in the feedline.

Adding altitude also overcomes obstructions that could easily strip
away the added "loss" of the line.

My buddy's 2M repeater is over a nearby hill from me (I am roughly 100
feet below its crest) and 10 miles away. I can hit it with a pocket
HT (100mW with a cheesy antenna) from inside my basement, but move
into another room and it's a morgue. A "better" antenna is hardly

going to do as good a job as the same poor one above ground level. A "better" antenna will not fit in the pocket, so "better" is entirely subjective with its objective analysis not so much very better.

Depends on the TOA. Around Phoenix, we had a mountaintop repeater
that we could hit better with a 1/4 wave than with a 5/8 wave when
we were close to the base of the mountain upon which it resided.
That's where we camped out a lot.

100. not cutting excess wire beyond antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2004-04-03 21:19:19 UTC
From: Dan Jacobson <jidanni@jidanni.org>
Message-ID: <87isggiwtk.fsf@jidanni.org>
Source record: 97354

Assume one has borrowed a spool of wire, on the condition that one is not allowed to cut it.

OK, say we'll make a folded dipole. Can one just ignore the unused portion still on the reel beyond the contact clamp? We should roll it away from the antenna a little, yes. Assume we have only used 1/2 the wire. I suppose effects go up as frequency goes up. Probably the best answer is to pick another design that will use the whole reel.

Bet Cebik never thought of this problem.

From: Dan Jacobson <jidanni@jidanni.org>
Message-ID: <87ad1sivb0.fsf@jidanni.org>
Source record: 97353

Assume you have tons of wire, string, and hilly treed land, and want to listen to FM 90 Mhz. Impressed with the 1/2 wave dipole nulling out competing stations, you think, "I am the owner of tons of wire, I will put my wire to work to pull it in even better."

What design will utilize my ton of wire at such a short wavelength? Don't tell me to trade my ton of wire for Yagi parts, as we are on a deserted island. Assume mom will be angry if I cut the wire more than once or twice.

103. a dipole made of two great sheets of metal?

From: Dan Jacobson <jidanni@jidanni.org>
Message-ID: <878yhciuof.fsf@jidanni.org>
Source record: 97355

Assume there is only one spot on your hilly land that you can pull in your favorite FM station, 90 Mhz, over the competition, and only with a horizontal dipole at a certain azimuth. A Yagi doesn't help, as we are depending fully on the null.

Assuming we are stuck with this position, how can we enhance our dipole? I am the owner of great sheets of metal. Can I put my great sheets of metal to use in e.g. a dipole made of two great sheets of metal?

I'm aware that there are off cases where the normal rules don't apply, but
in general, higher gain and a flatter pattern, is always better than lower
gain and heating the clouds..

I've not seen many hairpins out there, and they are just a small bit more to
build than the GP.
Why is that? Are they just not well known?

Commercial FM stations are vertically polarized, cause most of the people that listen are in cars. I have found this to be true in my homebrew antennas (at least around here). You might try changing the polarization, and see if that helps.

Not sure why you think a yagi won't help. A 3 or 4 el. yagi with a good F/B and proper polarization will be a big improvement over the end nulls of a dipole.

Using great sheets of metal for a dipole will increase the bandwidth, but that is not what you are looking for. Using the great sheets of metal for a screen reflector, or corner reflector could produce some big improvements.

I thought the FCC required equal EIRP of both vertical AND horizontal
polarization for an FM broadcast station? Did the horizontal requirement get
deleted?

Dan, Wire is so cheap and plentiful, if I wanted to put up a folded dipole,
the very last thing I would do is borrow wire with the stipulation that I could
not cut it.:-)

I don't know, but I bet LB W4RNL has not thought about cut or not to cut.

I don't know, just reporting on the results of my tinkering, I get by far the best signal with vertical polarization. I assumed that was becuse they wanted to target automobiles. Maybe the EIPR of the stations in both the vertical and horizontal planes in my area are not in compliance?

Bob,

I found a bit of information from this site, though
it is in French:

http://www.connectinfo.fr/ham/radio1.html

It has about 1 Mbyte of PDF's concerning multiband
antennae made from twinlead. It is certainly a lot more
than I have found by searching for "lattin" antenna.

I ran the text from the PDF's through
the Google translation page and it came out mostly
gibberish, but some parts are understandable (I hate
being ignorant of languages.)

I am no antenna expert at all, but it looks interesting.
I have not yet attempted building one, though I am
thinking of playing with a 2 or 3 band version.

Hope this is of interest to you.

Phil - N4GWV

The tuning was difficult but once tuned it wasn't half bad. I accomplished
the 'trimming' by addition of a hanging tail at the open end of the 'trap'
on a couple of the bands. You
have to take the velocity factor into consideration as well. Combine the

difficulty in tuning with the problem of support and you will soon put it
away! It was a fun experiment but not worth all the time and wasted
twin lead. By going to an open feeder you do away with the velocity
factor, but the trimming is still a pain. Support problems are further
compounded. If I wanted to carry a 10/15/20m antenna it might
be worth while for field day. The only reason I got involved was after
seeing Bob, VE6TE, now SK, running one and I was never one to
pass up a chance to play around with something intriguing!

You could make a slot antenna? ie cut a rectangle out of the metal sheet (say) 2" wide and a little over 1/2 wave at the op freq. From memory you'll get pretty close to 50/75r and the polaraisation is 90deg to the slot.

Doubt it helps but worth a mention..

Cheers Bob VK2YQA

I have been collecting data on the Lattin antenna for a long time.
I have quite a bit of interesting stuff, including a photocopy of the
patent.

It looks like William J. Lattin applied for a patent on this antenna
on Feb 13, 1948. The serial number of his application was 8,132. He
was granted patent #2,535,298 on Dec 26, 1950. There are 5 diagrams
used in this paperwork to help describe the Lattin antenna, including
1 vertical version.

I've made a couple of semi-serious efforts to build one, but no
success. I'm not too antenna tech. capable, nor do I have any
sophisticated test equipment, beyond an swr meter and a military grid
dipper, stuff like that. I've not attempted to model it.

I would love to see someone who understands the tech part of antennas,
and who has modelling knowledge and capabilities.....to give this
Lattin a serious effort.

I have been collecting data on the Lattin antenna for a long time.
I have quite a bit of interesting stuff, including a photocopy of the
patent.

It looks like William J. Lattin applied for a patent on this antenna
on Feb 13, 1948. The serial number of his application was 8,132. He
was granted patent #2,535,298 on Dec 26, 1950. There are 5 diagrams
used in this paperwork to help describe the Lattin antenna, including
1 vertical version.

I've made a couple of semi-serious efforts to build one, but no
success. I'm not too antenna tech. capable, nor do I have any
sophisticated test equipment, beyond an swr meter and a military grid
dipper, stuff like that. I've not attempted to model it.

I would love to see someone who understands the tech part of antennas,
and who has modelling knowledge and capabilities.....to give this
Lattin a serious effort.

Ah ha!! Cecil has proof that the universe will ultimately collapse into
the Big Crunch. He can prove proton decay!!!

20 years ago my Ph.D. Physics staff spent many lunch hours discussing,
heatedly I may add, the possibility of proton half life.

Thanks Cecil!! What's your source??

DD,

The purpose of the choke is to keep "antenna" currents off the
feedline below the antenna. It won't necessarily be helpful, because
having the feedline act as part of the antenna may not be a bad thing.
But it does help keep the system behaving like a dipole (or whatever
antenna is above the choke). There _may_ be some advantage keeping
locally generated noise out of the antenna if you prevent the feedline
from being part of the antenna, so it's usually safer to include the
choke than not...the probability is that the choked one will be better
than the unchoked one. It's generally more likely that having the
feedline act like part of the antenna will be a bad thing than a good
thing.

No need to worry about losses in the choke: some turns of the
feedline simply add the attenuation of that much feedline, nothing
more, so long as you don't physically damage the feedline.

Cheers,
Tom

Hi Lee,

Thanks for the patent number, it makes a world of difference between
conjecture and what "is."

For one, it quite plainly illustrates that the pdf file that dominates
most links falls seriously short at the drive point as I had figured.
It also quite plainly illustrates EXACTLY the method that Irv reports
in tuning it to make it operational:
On Sun, 04 Apr 2004 00:37:30 GMT, "Irv Finkleman"

<finkirv@shaw.ca> wrote:
> I accomplished the 'trimming' by addition of a hanging tail at the

which is also missing from the pdf treatment. This more or less
confirms my suspicion that the pdf treatment was a pipe dream.

I will look into the patent's model further.

My latest source is "The Five Ages of the Universe" by Adams & Laughlin.
"Recall that a slight excess of matter over antimatter was generated
during the first microsecond of cosmic history. The universe can have
more matter than antimatter only if some physical process generates
extra baryon number. But if such a baryon number violating process
can occur, the protons are doomed. It is only a matter of time before
they must decay."

Source record: 97222

Dan,
Folding, or wrapping the wire around it's self in effect
makes that doubled portion 'dissapear'. So, doubling the
excess wire until the unneeded portion 'dissapears', should
work. Or, just make a loop for the frequency you want. That
always uses more wire than a dipole...

It won't hurt you to have the choke. Basically it's purpose is to
isolate the antenna feed point form the coax transmission line.

On transmit it helps the antenna behave according to its design by
isolating the coax outer shield from it by presenting high impedance to
the RF current.

On transmit the radio generates a differential signal on the coax that
the choke will not prevent passing on to the antenna.

On receive it prevents noise from the AC power the radio is plugged into
from traveling up the shield to the antenna again by presenting high
impedance to the RF current on the shield. This prevents the AC system
noise from mixing with the signals the antenna is picking up and
conveying it to the radio.

The choke stops the common mode current on the coax shield and it will
not affect the signals the antenna picks up from the distance because

the antenna generates a differential signal not blocked by the choke.

Source record: 97223

Most of the FM stations broadcast circular polarization, but it seems
that more of the hoz part gets attenuated by trees more than vertical.
So if there is a shallow angle to the transmitter, through some vegetation
Vert seems more dominant.

But I think this changes with over-the-horizon, and it gets more Hoz,
but I have not measured this.

On the original question, you can add antenna patterns if they are phased
right.
You can put a piece of metal in the direct path to block signal, may go down
10 dB or so.
Metal could be screen wire mesh between dipole and unwanted transmitter 10
by 10,
centered to get phase null in the back.

Source record: 97226

we did testing on antennas inside and on top of car, about 6 dB difference
(better outside)
for Both TX/RX. with same antenna as on cell

problem is stubby not removable, something seems mismatched,

but on many cell phones the ground is really just some of the metal parts
inside, no good "ground" at all
so the antenna is only part of the radiating area, the cell phone and your
arm the rest of the antenna.

Which means it may be hard (with a cellphone) to get RF into/outof a coax to
an outside antenna, unless it has a real connector (most do not, cost too
much, no need for it)

Nonsense; a properly constructed yagi will perform far better at rejecting
the undesired signal and maximizing the desired one than any dipole.

Source record: 97227

Thanks for all of the suggestions, I finally got it worked out. If anyone has this problem, this is how you do it. You have to take the rotor plate out of the tower, install the rotor where the plug points at one of the tower legs. Put the plug on the rotor and reinstall rotor, plate, and cable in one piece. If you put the rotor on the plate in the tower, the cable will not go on. After it is installed, you can't remove the rotor cable. It will just barely work, and you have to be commited to get it to fit. Thanks again for all the advice and help.

I get the impression that this whole discussion about reception
difficulties for 90 MHz FM signals is hypothetical, rather than an
attempt to solve an existing real problem.

Are you sure about the Yagi being better than a dipole under the
circumstances described? He said to assume that he is on hilly land. The
predicted performance of a Yagi is far-field performance. If the
surrounding terrain is bumpy enough close enough, perhaps the
performance might be rather different. If the field near the director is
substantially different from that near the driven element, and the field
near the reflector is different from both of those, perhaps a Yagi might
do a poorer job of discriminating against unwanted signals than a
smaller, simple, dipole would do, since the field in the neighborhood of
the smaller dipole would be more uniform. I'm not asserting that this
would be have to be the case, but it seems reasonable to me that it
might be the case.

Consider, for example, how FM broadcast signal strength and cleanliness
can vary markedly as one slowly moves one's car just a few inches, e.g.
in heavy traffic. This can happen both in downtown skyscraper jungles
and in the more natural mountainous terrain near where I live (Greater
Vancouver, BC, area), though in the mountains the heavy traffic is
blessedly absent. Clearly far-field assumptions are unwarranted under
such circumstances.

cross posting eliminated
Kees:

I am always amused at all the responses one gets on these NGs, and yet no one answers the question asked. Having said that:

Coaxial cable is supposed to carry signals in electromagnetic wave form between the shield and inner conductor. It usually does that well. However, in addition to that, the coax itself looks simply like a big fat antenna wire on the outside. Now, your job, should you decide to accept it, is to keep the signals the outside of the coax collects from getting inside. And where might they get inside? At the top end, where the real antenna is connected. So, a choke on the outside at the top, which has no effect at all on the signals inside the coax, tends to isolate the outside of the coax from the antenna, so these unwanted signals and noises aren't coupled to the antenna and then on down the inside of the coax. BTW, some radios with poor shielding will benefit from an additional choke at the receiver end also, but that depends on the radio. A test to determine whether it is needed: Disconnect the center conductor of the coax and leave the shield connected. Hear any signals and/or noise? If so, add a choke.

'JJ',
'Windom' antennas work well if they are used/erected
properly. They aren't really any 'better' than any other
antenna used properly. The 'all band with no tuning' is
more 'sales hype' than fact. But, they do work.
I think the particular antenna you are looking at is
more accurately called an 'Off Center fed' than a 'Windom',
but that's sort of 'picky'...
'Doc

PS - I also think the price is sort of 'steep', for a basically
simple antenna.

I believe that today's "Windoms" are not true Windoms!!

Ah Ha! Blasphemy surfaces.

As soon as "Ice Out" and the end of "Mud" season occurs I will be
installing a 1930s version of the "Windom".

Used one from Massachusetts with results equal to a dipole but simpler
construction.

My 1956 ARRL Handbook says that a Windom is fed with a
single vertical wire. If an antenna with Windom dimensions
is fed with a transmission line rather than a single vertical
wire, in the 1956 ARRL Handbook, it is called an "Off Center
Fed" dipole.

138. Lattin antenna.....more info sources

Newsgroup: rec.radio.amateur.antenna
Date: 2004-04-04 17:07:04 UTC
From: carkenord@juno.com
Message-ID: <4346b55e.0404040907.73bc4ac5@posting.google.com>
Source record: 97239

The following is some of the info I gathered in my attempts to understand and build a Lattin. As I said in my previous post, I was never able to get it to work as Mr. Lattin described. I wish that when I tried to build it, I would of had access to todays "Antenna Analyzer" test instruments.

It has been patented, filed Feb 13, 1948. Patent # 2,535,298 My local library had the patent on microfiche, and I was able to get it copied. I have a copy of his patent, with illustrations/drawings, on file here.

Lattin described this antenna in QST in December of 1960.

July 1960 issue of "CQ" mag has a related antenna project, by Richmond, W1CEJ, called "A Portable Dipole"

Vincent Lear, G3TKN has also worked with the Lattin design, and was published in RSGB.

July 1992 issue of "73" mag has another article "Six-band linear trap antenna" by Brumbaugh KB4ZGC.....using approx the same idea.

September 1986 issue of "73" mag has Lattin type antenna project described...."The Texas Tango Antenna" by Garrett K5BTV.

Maybe the above info will stimulate some more experimentation and/or modelling of the
Lattin. I sure hope so.

139. MFJ-921 tuner question

Newsgroup: rec.radio.amateur.antenna
Date: 2004-04-04 17:41:18 UTC
From: Ken <cprstn54zz@att.net>
Message-ID: <voh0709frvo13bp1gva8cfcc1766ue01cp@4ax.com>
Source record: 97240

With a [DC-500MHz] dummy load on my new MFJ-921 2M tuner, both
adjustable capacitors have to be set at around 3 to get SWR=1.0, with
the minimum being quite sharp.

I took off the cover and verified that cap settings of zero are indeed
minimum capacitance.

See: http://www.hy-gain.com/man/mfjpdf/MFJ-921.pdf

Shouldn't both caps be at the minimum setting for SWR=1.0 with a dummy
load connected? What does it mean if I need to add capacitance at
both points to tune a dummy load?

Should I reset the knobs so that they show zero when a dummy load is
connected?

>the smaller dipole would be more uniform. I'm not asserting that this
>would be have to be the case, but it seems reasonable to me that it
>might be the case.

Entirely unreasonable for the following reasons:

The spacing between elements of a 90 MHz yagi is about 2 to 3 feet. It is
hard to imagine a 3 foot wide hill.

In other words, it would take some rather bizarre terrain to have a
different effect on the driven element than the director.

Further, the far field at 90 MHz is about 10 feet or so; one would
hope the antenna is at least 10 feet off the ground and the next
hill is more than 10 feet away.

With a dipole, you are depending on the null to minimize the undesired
signal and have little gain in the direction of the desired signal.

With a yagi, you still have the null (assuming a proper yagi) plus
additional gain in the desired direction. The net result is the ratio of
the signal strengths of the desired to undesired signals becomes greater.

>Consider, for example, how FM broadcast signal strength and cleanliness
>can vary markedly as one slowly moves one's car just a few inches, e.g.

>such circumstances.

Clearly, far field assumptions ARE warrented under such circumstances.

What you are seeing is multiple reflections (in the far field) off the various structures.

Yet another reason to get the antenna high; i.e. above the influence of such structures.

I should have probably also mentioned that making a dipole from
sheet elements mostly effects the bandwidth and has very little
effect on either the gain or the pattern.

Search the web for bat wing antenna for more info.

Agreed. With a Yagi one might get the best desired-to-undesired signal strength ratio by pointing the antenna somewhat to one side or the other of the transmitter. This could reduce the "desired" signal somewhat, but could put the "undesired" signal path right in one of the antenna's deep nulls. Most Yagis having a modest number of elements have a wide-enough beam angle to give you a fair amount of wiggle-room in the aiming.

Just my experience. Today's cars seem to have a lighter sheet metal
thickness than days of yore.
I used a Greenlee punch on my 91 T-Bird.
Curses - put a dimple in the roof.
Forget the hole saw -- dimples as well with too much pressure.

I Asked around and the gurus say to use a Motorola tool for this -- outfits
that do police, fire installations etc will have these.

Be sure to seal the opening after installing the roof mount -- the same
outfit can advise. I found the o-ring to be not good enough

I like the roof mounts -- makes a good connection with the car metal.

And you can swap whips easily -- for 2M I use a 1/4 wave around town and a
5/8 for trips.

Really haven't found much 440 activity while traveling, so I use a 2M 5/8
wave and watch the clearance in parking garages - hi hi.

Haven't seen a comparison of mag to roof hole mount performance - but mag
mounts worked OK on a rental car I got for a trip back east

Good Luck

I wonder about this one working all bands without a tuner. I need
something simple for the moment that I can quickly put up and work
several bands. I think this one is what is/was referred to as the
"Carolina Windom"? Thanks to everyone for the replys, I think I will try it.

The best way to get a 1:1 SWR with a tuner connected to a dummy load would be to put the tuner in bypass (if it has one). Adding a tuner between your dummy load and swr bridge will make the bridge see something besides 50+-j0 ohms even with the caps set at minimum.
What you are having to do is adjust the tuner until the bridge once again sees 50+-j0 ohms. Apparently with the 921 this is with the caps around 3.
>Should I reset the knobs so that they show zero when a dummy load is
>connected?

Not unless you just want to. The numbers are for reference so you can quickly reset the tuner for a given antenna or impedance.

Hello,

I use a home made (low $$$) OCFD type antenna for 80-10m + WARC of the Fritzel FD4 2kW version's length; fed with 300 Ohms twin lead and a 1/6 current balun out of the shack. It needs only minimal AT tuning for 20m and the WARC bands, 15m is no problem due to a second shorter OCFD cut for 21 MHz at a common feed point.

For 160-10m operation a 2X20m Levy antenna with Levy tuner and 15-20m 300ohms twin lead would be a better choice.

Hi,
I am searching for a rubber whip antenna, which
can be mounted to a car, about 15 cms (about 6 inches)
long. The antenna should bounce when the car moves.
The technical specifications are of no interest, because
it would be only for the optic.
Once there was such an antenna made by BOSCH Part No
8 698 121 751 (STAB 461 F). Unfortunately that antenna
isn't available anymore.
Tim

This tuner dosen't have a position to bypass the unit. I would guess the
reason for having to add some capacitance is because there are three
fixed inductors in series and you have to tune out their reactance to
get 50 ohms.

That's a really small car, is it one of those R/C jobs? Last Christmas they were selling some that were only 3 inches long. Maybe you could see what kind of antenna they used on the 3 inch long cars. :-)

Did you misplace a modifier or is the car really about
6 inches long? - perhaps a model car?

Unless you have a tube type radio where the radio itself may need tuned to a 50 ohm output, the dummy load should be connected to a bypass port on your tuner. Then the settings of the capacitors is unimportant. You then use the dummy load to make adjustments to your ALC level, mic gain, processor gain, etc without transmitting over the air.

158. aerial coupling and nec2 - I do not understand my results

Newsgroup: rec.radio.amateur.antenna
Date: 2004-04-04 23:34:43 UTC
From: stuart macgregor <stuart.191@ntlworld.com>
Message-ID: <pan.2004.04.04.23.34.43.492290@ntlworld.com>
Source record: 97259

I wrote a little ruby (nice interpretive language) wrapper round the C port of the nec2 program, and began happily generating simulations. So far so good. (When I am finished I could offer it to anyone interested)

I am new to EM stuff - so here comes what is probably a silly misunderstanding:

Consider an array of similar aerials (antennae).

Since the situation is linear, I would expect the currents received from a plane wave signal to be linearly related to the currents which would be obtained at each element position if there were no aerials at the other element positions (assuming the effect of an aerial on its surroundings is due solely to its current, and you can linearly add a cancelling current and thus remove it)?

The relationship can be expressed by a symmetric (reciprocity) coupling matrix which should be independant of the incident plane wave direction?

For a regular array on a circle the matrix should be toeplitz, by symmetry, and constitutes a cyclic FIR filter which will yield the coupled signal observations from the (free) field values at the element positions (to a complex scale factor). It can thus be found by division of the FFTs (of the loaded simulation currents vs open circuit simulation currents or vs free field plane wave calculation) and inverse FFT.

When I try this - for example with a regular 3 element circular array of resonant dipoles - I find that the FIR coefficients derived do indeed convert from free field pattern at the element positions to array currents, but only for the angle from which they are derived. The relationship seems to be signal dependant :-(. For example the plane waves in the opposite sense (180 deg) have a quite different coupling matrix (mostly in phase).

Can anyone point out my mistake, this is really bugging me. I have tried increasing the number of segments to silly levels, to no avail. For 2 dipoles it works, more and it does not.

Message-ID: <il1cc.1034$BF2.177839@news20.bellglobal.com>
Source record: 97261

I'm not a technical expert like many on this group, but I have used a Antennas & More TNT-Windom (OCF dipole) for a few years now both in an inverted-vee dipole and "windom half-square" configuration up 35' (33V'-66H'-33V') set up N-S. This TNT model has a choke balun near the feedpoint that helps with RF on the coax.

The best set-up was the half-square which had low angle broadside gain E-W on 40M and on some higher bands. Good 80M coverage given the height too and excellent DX above 40M. Good matches everywhere (17M & 12M too, more difficult on 30M, 15M and 10M) but my built-in tuner on the TS450SAT did it all regardless. I even used an external tuner for 160M tuning - poor performance, but okay for 400 miles around - for extra multis in contests.

I think this model is better than the Carolina Windom because the Carolina vertical element needs to be 15' from any metal - according to a phone call to the manufacturer. I hang from a TV tower now so the tower proximity would interact much more the Carolina model.

This was my 2nd commercial purchase to replace a hurting G5RV and I feel it works MUCH better than the G5RV it replaced. I still use it for 80M-40M portable contest work.

My Handbook shows the same thing. This only confirms that both of us have been in ham radio too long!!!

My first Novice 80 CW antenna was a true Windom. W1GID, Ralph Tedford, one of my early Elmers, installed it for me. I ran an ARC 5 transmitter into it. Funny thing though, I kept getting tingling sensations off the key until I lengthened the feed line about 25 feet :-)

I earned my first award with that radio and antenna: "WATV"

Deacon Dave, W1MCE for 50 years

Looking over the replies to this post makes me wonder where the helpful ham hand is lurking these days. This poor guy just wants to know about plans and materials for an antenna to build and all but one reply tells him he doesn't want one or you should buy this one or he's stupid for considering one or I can get into this repeater with that antenna, bla, bla bla. It can be made with the same components as an SO-239 1/4 wave ground plane but with a little more wire with a cork screw turn at the bottom. Doesn't anyone have the simple plans for this guy?

166. COLUMBUS OHIO, where to stay and be near OSU and still have a little DX?

Newsgroup: rec.radio.amateur.antenna
Date: 2004-04-05 02:15:21 UTC
From: Bob <nowhere@nospam.org>
Message-ID: <ni3cc.4591$wq4.396012@news20.bellglobal.com>
Source record: 97269

I'll be attending a function at OSU in early July, and I'm looking for some advice from local ham residents and/or hams who are very familiar with the area near Ohio State University.

I'll be bringing my FT-817 along and it would be nice to find a multi-storey hotel that has balconies for each room and not be next to some horrible HF unfriendly influence. (not that cities in general are particularly good for HF, but a hotel right next to a power substation or AM radio station transmitter would not be my first choice, and a 3 storey place sandwiched between much higher office buildings would not likely be my second ;)

So, the closer to OSU the better, because it would be nice to be able to walk there each morning for to attend the lecture series, within a mile walking distance would be okay.

A balcony would be nice (weather cooperating that is) for early morning / late evening QRP and would allow me to put some sort of antenna outside of the walls of the structure.

I realise this might be asking for a lot, but I've never been there and as such I'm completely uninformed about the area, so I thought this might be a good place to ask "hams who know" what they would like if they were there.

Thanks for reading!
Bob

Dan Jacobson wrote:
"A Yagi doesn`t help, as we are depending fully on the null."

Dan also wrote:
"I am the owner of great sheets of metal."

If "your favorite FM station, 90 Mhz," differs in direction from its interfering "competition, and only with a horizontal dipole at a certain azimuth", a Yagi made by adding a director and a reflector should increase signal to noise ratio.

Great sheets of metal can be used as a corner reflector for a favored dipole. A 90-degree reflector can give about 10 dBd gain. A 60-degree reflector can give about 2 dB more gain than the 90-degree reflector.

J.D. Kraus documented the corner reflector, Proc. I.R.E., 28, 513-619, November 1940. Consult Kraus, "Antennas" for complete information, 1950 edition, page 328.

I prefer pi-net tuners - two variable caps to ground and a variable
coil in series in the middle. Easy to build and is a low-pass filter
to boot.

Yes you can build one if you can get the parts. There is nothing very
special in most designs. The ARRL Handbook has a few in it. I am sure a
Google search would lead to many.

Hi Cecil
Hi "Matthew&Wendy"
I prefer resonant antennas and transmission lines that match them.
You just can't beat a resonant antenna for radiation.
Tuners squander AT BEST 1 or 2 db.
At WORST (as Cecil has posted here regarding "shootouts") >10 db.
So build your antenna resonant, match it, and don't bother with a tuner.
If impedance transformation is necessary, use a transformer;
That's why they're called transformers.
That's what they're for.
Just my 2 cents.
73
H.
NQ5H

PS
Wire antennas are CHEAP.

I prefer non-resonant antennas and transmission lines that resonant them. :-)

> You just can't beat a resonant antenna for radiation.

Maybe not, but you can equal them. A tuned transmission line resonates
the antenna system.

> Tuners squander AT BEST 1 or 2 db.

That's why I don't use a conventional tuner.

> So build your antenna resonant, match it, and don't bother with a tuner.

Or build your antenna non-resonant and match it with a series section
transformer.

> If impedance transformation is necessary, use a transformer;

IF impedance transformation is necessary, use a transmission line
as the transformer. :-)

Patents don't last forever, and the beverage antenna has been around
forevern'forever. You can build a duplicate of anything you want to,
you just can't "manufacture for sale". Wish I had the property here on
the Gulf Coast for a beverage. I'm just able to get my multi-band
dipole on my lot by having an L shaped flat top. It works pretty good
so I shouldn't complain.

Eh? You mean a 1ï¿½-wave (non-resonate) dipole radiates less than a
ï¿½-wave resonate dipole?

Strange in that a 1ï¿½-wave dipole has 3 dBd gain.

Actually I do have plans for a colinear 5/8 over 5/8 2 meter antenna;
all you'd have to do is omit the phasing coil and top radiator. This
one is built from wire on an SO-239.

To the original poster - I can scan the sketch & email it to you, let
me know if you'd like that & it's a done deal.

Do antennas have gain or do they have directivity?

Bill

This is just something to think about. I would have thought that
"squandered" power wouldnt necessarily be "dissipated".

I suspect you would be in for a surprise at field day..
What about your balun/choke connection? I assume you will be running coax to that choke, and then to 50 ft of ladder line? And the variable cap on the antenna side of the choke...How convenient... All I can say is why? There is no way on earth that setup is *more* efficient than a coax fed dipole. It may be *fairly* efficient, maybe even quite so if you are real lucky, but it's not going to be as good as the full size dipole fed with good coax. No way. The only real loss I have is the loss of the feedline "213", and on 80m, it's about as good as ladder line.
Dunno...I think complicated gimmicky setups that are inferior to the ultra simple coax fed dipole are kind of silly. :/ But to each his own. If it were better, I could see it. But it's not. It's inferior. If it were not, I would be using one here at the house. Why would anyone want to do more work, for something a step in the wrong direction? Boggles me mind...I've never seen why people want to use smaller or compromise antennas when you have the whole wide outdoors to string up anything you want. The "average" storebought G5RV is pitiful on 80m compared to the coax fed dipole. Not even a real contest.
But everyone ignore what I say. I'm really fibbing, and just messing with ole Cecils head....I suggest all field day op's on 80m use G5RV's, windoms, isotrons and EH antennas. If you all follow my advice, I might be able to mop up quick, and be able to go home early and get some sleep in my cool, bug free, air conditioned bed.. :/ MK

>
> Why would he be better off with a 1/4 wave, with it's large vertical lobe?

Cuz it's easier decoupled with it's 1/4 wave radials, and is less
likely to have feedline radiation than the funky 5/8 antenna with 1/4
wave radials. In direct comparisons here, the 1/4 GP was a good bit
better than the 5/8 with 1/4 radials. The maximum gain of an elevated
1/4 wave GP on 2m, mounted at 35 ft at the base, is appx 6.2 dbi at 3
degrees. The maximum gain of a 5/8 GP with horizontal 1/4 wave
radials, at the same height, is about 4.7 dbi at the same angle. And
this does not yet take into account any decoupling problems! If the
feedline radiates, any gain on the horizon is likely lost as the
pattern is skewed up off the horizon. The average 5/8 antenna is
ruined by using 1/4 wave radials. A 5/8 should be paired with a mirror
image 5/8 to function properly. IE: dual 5/8 collinear such as the
isopole, etc...
And decoupling must still be used even on those. I agree with one
thing Richard said about height and a 1/4 wave..If you get the tip of
the 1/4 GP at the same height as the tip of a tall dual 5/8 collinear,
there is little real difference between the two. And the dual 5/8's
collinear is better than a 5/8 GP. 2m is real critical as far as the
low angles used, and also to the effects of feedline radiation
lowering the gain at those low angles. Now on 10m, many times I do
prefer a 5/8 GP over a 1/4 GP, but there the angles used are less
critical.
If your 5/8's works, I wouldn't worry much, but in comparing them in
A/B tests, "at appx 35 ft" I've never seen a 5/8 GP with 1/4 radials
beat a 1/4 wave GP with 1/4 radials. I once built a fancy 5/8 GP with
a nice larson coil, lots of 1/4 wave radials, etc...Was a super

dud...I tore it up the 1st day and went back to a 1/4 wave. The 1/4 wave was an average 3-4 S units better on local rptrs, and simplex. About the same difference as comparing a undecoupled ringo ranger, to a decoupled ringo ranger 2... MK

Sure, if he really wants to use an inferior antenna, I can tell him
how to build it. It's simple. A 5/8 wave radiator, and about 4-5 turns
of coil on a one inch form for matching will get him fairly close.
But I don't recommend one. You wouldn't get me running a 5/8 GP on 2m
for anything. It's like G5RV's on 80m...They usually suck...So do most
5/8's GP's on 2m...:/ But don't take my word for it. Compare them with
an antenna switch and see. The only time I ever see a 5/8's beat a 1/4
on 2m, is if they are nearly on the ground. And I think thats just a
line of sight deal... MK

A nice rhombic with ladder feedline? You will also need a
resistor though. Do you have a pencil in that island?

:-)

It's "resonate", Cecil, and the antenna still won't be resonant.

>
> > You just can't beat a resonant antenna for radiation.
>
> Maybe not, but you can equal them. A tuned transmission line resonates

When you get a lossless line. And the antenna still isn't resonant.

Antenna resonance implies a purely resistive impedance at the feed point.
Both 1/2 wave and 3/2 wave dipoles are resonant.
I don't know what a "1/4-wave resonate dipole" is.
A dipole is 1/2 wavelength long at it's fundamental resonant frequency.
"Gain" is merely a re-distribution of the radiation pattern.

Nonsense huh?
OK
Load up your rig at 1500 watts key down with a tuner.
Measure the tuner's temperature.

Icom specifies the insertion loss for the tuners in my 756PROII and PW1.
Icom claims less than one decibel. (After tuning)
The loss is easy to measure and at 1KW it is indeed well over 100 watts
warming the PW1's innards when it could be radiating away from my SteppIR.
So I leave the tuners out of line and adjust the antenna for SWR = 1:1.

Thanks for the comments everyone!

I'm aware of the performance issues for short antennas, but at least I won't have to remove it to park my car in the garage :-)

How about the COMET B-10? Anyone using it?
Is there anything similar, around the same size with a little better performance?

thx,
Andreas

Interesting. You obviously have developed a far superior measurement
technique than most antenna engineering firms, and maybe even NIST. Your
results disagree with pretty much everyone who measures antenna gain
professionally, and the ARRL handbooks, but hey they must all be wrong then.

Though it's entirely done in the HF spectrum, a pretty detailed analysis is
presented here:
http://www.cebik.com/58-3.html
A good ground, and cleaner near-field space, is easier to come by at VHF and
UHF, so I would expect results to be somewhat better than what was seen here
even at the high end of the HF spectrum.

If you google a bit, you'll probably find some articles on converting a CB
antenna to a 5/8 2 meter antenna.

Someone sed,

"You just can't beat a resonant antenna for radiation."
==========

PHOOEY! Some of the best antennas are NOT resonant, and shouldn't be.

I use my 130-ft doublet on 40 m where it is one wavelength long. Has
theoreitical gain of about 1.8 dB. This is NOT a resonant antenna.

Mark Keith wrote:
> What about your balun/choke connection?

W2DU choke, virtually lossless. The tuning cap is also virtually
lossless, much more so than a tuner with a coil.

> The only real loss I have is the
> loss of the feedline "213", and on 80m, it's about as good as ladder
> line.

It's about as good as open-wire line with a 10:1 SWR. The matched line
losses in 100 ft. of RG-213 are higher than the unmatched line losses
in 100 ft. of open-wire line with a 10:1 SWR on 80m.

According to Wirebook II, the matched line loss for RG-213 is ten
times higher on 80m than the matched line loss for open-wire line.

> If it were better, I could see it. But it's not. It's inferior.
> If it were not, I would be using one here at the house.

You are so biased, you wouldn't use one if your life depended
on it. :-)

> Why would
> anyone want to do more work, for something a step in the wrong
> direction?

It's a step in the right direction, Mark, toward an all-HF-band
antenna. I modified my G5RV yesterday to work well on all eight
HF bands plus 6m. Field strength measurements indicated it is
virtually identical to my 130 foot dipole on 80m.

> The "average" storebought G5RV is
> pitiful on 80m compared to the coax fed dipole.

Mine is virtually equal to a resonant dipole. Your "average" storebought
G5RV must be poorly designed - maybe lacking a balun - maybe using RG-58
coax - maybe using the wrong length of the series section transformer.

> But everyone ignore what I say. I'm really fibbing, and just messing
> with ole Cecils head...

I asked for some scientific proof of what you say. All you responded
with is prejudice and hand-waving. Please take time to calculate
the matched line losses in RG-213 Vs the unmatched line losses for
open-wire line and you will change your mind (if you are rational).

So what? If you move off the resonant frequency, your antenna still isn't resonant. I'd rather have a resonant antenna system on many frequencies and many bands than an antenna system resonant on only one frequency.

>>IF impedance transformation is necessary, use a transmission line
>>as the transformer. :-)
>
> Not the least lossy approach.
> Matched impedance = max power transfer.

Depends upon how much money you want to sink into your coax. Open-wire line with an SWR of 10:1 will beat RG-213 in the loss department on 80m. It takes 9913 to equal the performance of open-wire line with an SWR of 10:1 on 80m and 9913 costs about three times as much as open-wire line.

And with open-wire line, one can enjoy all eight HF bands immediately, and not have to spend two days cutting and trying a fan dipole.

Dear Bill,
Your figures and your terminology are 100% correct. Anyone who has an amplifier capable of delivering 1500 watts of carrier power, continuously, for any appreciable amount of time would, indeed, encounter a smoking mess. Fortunately, hams don't usually run that kind of power, but it does explain why so many tuners found at hamfests have very obvious damage to the variable inductor coil.

Look again, Danny said a 1.25 WL dipole, a non-resonant length
dipole known as an extended-double-Zepp and known to have about
3 dB gain over your 1/2WL resonant dipole. With about a 0.2WL
series section transformer made out of open-wire line, the
non-resonant EDZ resonates as a system and will beat your
resonant 1/2WL dipole in its favored direction.

Guess the answer is 'yes'. :-) Seriously, directivity doesn't
include efficiency. Gain includes efficiency. If an antenna
could be 100% efficient, the directivity and gain would be the
same.

Dan Jacobson wrote:
"What design will utilize my ton of wire at such a short wavelength
(3.33 meters)?"

Dan also indicated he would like to minimize cuts in the wire.

An obvious contender would be an axial-mode helix antenna which just stretches out a coil of wire with no cuts at all.

The inventor, J.D. Kraus, includes chapter 8 of his 3rd edition of "Antennas", The Helical Antenna: Axial and Other Modes, Part 2.

Kraus has an example in Fig. 8-54(a) on page 281 of an 80-turn axial-mode (end-fire) helix with a gain of "24 dB". (This is surely dBi as Kraus doesn`t specify dBd.)

There would also surely be a few pounds of wire left over unless the wire is very large indeed. It might be bonded for a reflector or other purposes.

Best regards, Richard Harrison, KB5WZI

Hello:

Do listening only.

Presntly using a random length wire strung around the 4 sides of my attic
(probably about 40 ft x 25 ft x 40 ft x 25 ft; resultant loop left open at
end)

Works fairly well, but would like to try and do better.
Might bite the bullet this spring, and try putting something outside.

Whatever I try, I want it to be omni-directional, and be fairly broadband in
freq. coverage; say from 500 KHz to 30 MHz.
No Tower.

a. For something relatively straightforward, what type or brand would you
suggest ? Worth doing over what I now use indoors ?

b. Any probable advantage to taking the most simple approach, and ust
stringing a 150 foot straight wire outside
compared to what I now have in the attic, assuming same height.

c. regarding nearby lightning strikes and resultant voltage surges picked
up by the indoor antenna wire:
does the house roof off any meaningful protection (when dry) compared to
a wire strung outside?

BTW: For a straight 150 foot wire, at a height of about 25 feet, is it most
sensitive perpendicular to the wire axis, or along it ?
How does the answer depend on received freq. ?

Much thanks,
Bob

Hi Bob,

You fail to mention the quality of your receiver, I will proceed as if
it were middle of the road ($200-$400).

Your open loop should be coax fed with a choke at the feed point to
reduce noise from the house coupling in (unless there are noisy
components in the attic).

At the other end of the coax, back at the receiver, you should be
using a tuner to perform matching to DX and rejection of strong AM
stations that can seriously de-sensitize you (this is the hidden DX
killer).

Connect to a suitable ground. This sometimes does wonders for
sensitivity. It also sometimes introduces ground loop problems
(solving those problems is worth while to keep the ground).

You already have "enough" wire. Your future goals should be to move
it away from the house if you suffer noise. You would also stand to
gain if you can elevate it higher. Either way, more wire is unlikely
to bring any fantastic return. This has exceptions, of course, if you
want to try Rhombics, or Beverage Antennas (these require serious real
estate for HF however).

Maybe so if using a simple antenna switch to A/B test is superior...

Your
> results disagree with pretty much everyone who measures antenna gain
> professionally, and the ARRL handbooks, but hey they must all be wrong then.

No, they do NOT disagree with most who have a clue. BTW, those
"results" I gave you with gain numbers were from modeling.
>
> Though it's entirely done in the HF spectrum, a pretty detailed analysis is
> presented here:

HF? Thats the problem....You can't apply the performance shown on HF,
and expect it to pan out on 2m. The decoupling problem will rear it's
head on VHF.

> http://www.cebik.com/58-3.html
> A good ground, and cleaner near-field space, is easier to come by at VHF and
> UHF, so I would expect results to be somewhat better than what was seen here

A good ground is not the whole answer. Decoupling is more important at
those higher frequencies.
>
> If you google a bit, you'll probably find some articles on converting a CB

Why would I need to do that? I already done that before. I've built
enough 5/8 antennas to choke a horse. Maybe two or three. Thats why
I'm fairly comfortable with what I say.
I'd like to ask one question. Have you ever actually compared the two
types at the same time using a switch? MK

207. Through-Glass Antenna/Ford Taurus

I have a 2000 model year Ford Taurus wagon, and am thinking about mounting a through-glass antenna on one of the back side windows. Yes, I know---a roof mount would work better, but I would have to get a hole punch and a divorce lawyer to do it ;-)

Does anyone have any practical experience with this set up? Does the window tinting cause any problems on 146 MHz or 440 MHz? There is a completely dark (opaque) band around the edge of the window. Should this be avoided?

I have seen Taurus wagons with cell phone antennas on the back side windows, and was wondering how it worked on the ham bands.

One note...There is only one case on VHF where I often prefer a 5/8
over a 1/4 , and that is on a car when roof mounted. The 5/8 will
usually "picket fence" less, if you are in an area that is all flat
terrain. But as far as elevated ground planes at the house, I prefer
the 1/4 wave anyday. If I use 5/8 elements at home, it will always be
a dual 5/8 collinear of some type. Not a GP with 1/4 wave radials. MK

I have a new in box cell phone glass mount antenna. It is one of the "full size" 800 MHz type with a self supporting air wound coil.

How well would this work on 146 MHz, if at all? 440 Mhz? Dual band (146/440)? Is anything more than trimming the length required?

Yes, you feed it at the corner where the flat top ends and the vertical leg goes down. Keep the vertical leg at least 10 feet from any tower. I use two tall trees for my 80 half square. The coax should come down away from the vertical leg. The best way is to have it come down splitting the angle between the vertical leg and the center. Its not critical however.

Not very well.

The larsen glassmounts made for 2/440 are roughly comparable to a 1/4 wave,
but I would say somewhat less gain. I've never measured mine.

I'd expect the cell version to be way short, and the coil is probably wrong
for this app too.

Then again, if it's bad enough, the coil might not make much difference. :)

I have a pair of the larsen glassmounts for SSTV and APRS, and I'm
seriously thinking of converting to a pair of normally mounted antennas. 50W
up that pipe dosen't get much done.
If height weren't a problem, I'd go for a pair of SG-7900s, but they are
challenging to mount, and not very forgiving of low hanging trees or other
obstructions.

Hustler makes a 5/8 wave 2M antenna they call the SF-2. HRO sells them for
$14.95.
At that price the only reason to make one is "for fun" but that's
worthwhile.

Just get a mag mount, that is a magnetic mount.
You can change out the rod for longer wavelengths
put on roof, or trunk, take off when done
(doesn't look good on the hood,)
your ham store should have them too.

John Smith wrote:
> Just get a mag mount, that is a magnetic mount.

One nice thing about a mag mount is that if you hit something
pretty hard, it just falls over but keeps attaching itself
to the vehicle body. I stopped worrying about parking garages,
trees, etc. I could hear it fall over and when everything was
clear, I simply stopped the vehicle and straightened it back
up. Sometimes the simple way is the best way. Life doesn't have
to be complicated.

It's more decoupling than anything. Although the usual 5/8 GP with 1/4
wave radials is a flawed animal from the git-go. I think the best
article to describe the effect is from a Dr. Reynolds , "I think thats
the name anyway", that wrote an article for AEA about this problem.
They put out a small brochure with the article and some pictures. They
described the problems with most of the common verticals used. IE: 1/2
waves, 5/8's, and collinears. The result of all that led to the
development of the AEA isopole. Probably the best decoupled dual 5/8
collinear ever designed. And thus , the highest performing compared to
less well decoupled competitors. Thats why cushcraft modified their
ringo ranger, and added a decoupling section, and renamed it the ringo
ranger 2. The effects of a lack of decoupling was glaring when
compared to an antenna of the same appx size, using good decoupling.
The RR was also an appx dual 5/8, although slightly perverted in
dimensions...The RR2 is a good antenna. But the isopole will still
usually beat it. The 5/8 GP or other poorly decoupled antenna does
have the rare chance of the feedline currents adding in phase and
creating some gain, but this is like a one in twenty chance...Like
going to Vegas...Doesn't usually work out that way for most people.
Never did for me...I've never had an elevated 5/8 GP on 2m that was
worth a hoot. Not a one...
Only on a car were they ok. But you look at a car...It's large enough
to usually provide a lower 5/8's of sorts, and also there is no
feedline radiation to skew the pattern upwards. The feedline radiation
if any, is shielded by the car body.
HF is a whole different story. On 10m, a 5/8 GP is best over both a
1/4 wave and a 1/2 wave. I've tested this many times in the real
world...
HF is less critical as far as using a real low wave angle, and also
the average angle used , even locally, is probably slightly higher.
But it doesn't apply to VHF or UHF. It's a whole different world
there, and feedline decoupling is by far the most critical part of a
good antenna. Not brute gain numbers. It won't do any good if the gain
is not where you need it. And thats under 5 degrees for local VHF. MK

Possibly

There is a completely dark (opaque) band around the edge of the window.
Should this be avoided?

YES

>
> I have seen Taurus wagons with cell phone antennas on the back side windows,
> and was wondering how it worked on the ham bands.

Cell phone antennas perform poorly on 2 & 440 <grin>. I presume you
mean the mounting not the antenna. Through the glass should be fine.

I use a Larsen Through the Glass and there is no noticeable loss of
signal. Theoretically, the loss is about 0.5 to 1.0 dB for clear glass.

There is a mutual coupling term between the elements of an array antenna.
This can be minimized by proper spacing, and by eliminating some of the
elements.
Looking back at the array - (from each angle) -- The pattern is a linear
summation of the each of the currents induced by the emitters (using complex
numbers, i.e. magnitude and angle, distance etc)

I use a homebrewed Windom antenna as my sole HF antenna. Works VERY
well on 80, 40, 30, 20, 15 and 10 meters. Tunes easily with an
MFJ-941D tuner, and performs very well in all directions. It's a
little twitchy on 12 and 17 meters, but by reducing output power on
the transmitter, it's useable...

Message-ID: <Yqqcc.4078$Fo4.44247@typhoon.sonic.net>
Source record: 97132

I have a CC Radio Plus (Sangean) AM/FM/TV/WX radio (from C. Crane Co.) I enjoy broadcasr band DX'ing and this radion does a super job with just it's built-in ferrite antenna. I have logged AM BC stations from practically every state east of the Mississippi.

Best reception is, of course, at night. But.... for some reason WABC (New York City) comes in poorly at night even though it's xmitter is only 80 miles away. The signal fades to next to nothing and then increases to very loud but extremely distorted then will be loud and clear for a while. (During the day this station's signal is fine.) On the same evening, stations in Georgia (WSB, Atlanta), Illonois (WGN, Chicago), Michigan (WJR, Detroit), etc., etc. come in fine 90% of the time.

Do I need an external antenna for the closer WABC?????

Thanks,

Dave Pitzer

Source record: 97133

Dave:

I don't know the specifics of WABC, but many radio stations have different power and antenna patterns for night time operation than they do for daytime. I would suppose that WABC is a clear channel station that can transmit 24 hours a day at 50KW (50,000 watts). Even as such, the antenna pattern may be nearly omnidirectional during the day, and highly directional north and south at night, and you may be sitting in one of the "nulls", hence you get poor reception at night.

As you are close by, you may be able to call them directly and ask what their power and antenna patterns are, if you are interested in finding out if this is the issue...

Of course, atmospheric conditions change dramatically after the sun goes down, and they could be accounting for the signal fluctuations you are experiencing...

Thanks

Hello,

Maybe Cushkraft antennas... I have a second hand AP8A since 1998 and it works quite good on HF.

For V-UHF, you can homebrew your own antenna or step up for the cheaper Diamond clones by TSB (or others).

Mark makes a good point. Those with EZNEC or other modeling program might try this -- build a model of a ground plane antenna, and do an elevation plot. I'll describe the process with EZNEC, but you can do the same with other programs. With EZNEC, start with the example description VHFGP.EZ, and change the Plot Type to Elevation. Click FF Pat to run a pattern. In the 2D window, select Save Trace As, enter a name, and click Save. Then, from the junction of the ground plane and vertical wire, extend a wire downward for 3/4 wavelength, by adding a wire (in the Wires Window) with end coordinates 0,0,5 and 0,0,4.25 wavelengths. Give the new wire 15 or so segments. Change the Units to Inches or Millimeters, and make the diameter about equal to the outside diameter of your feedline coax. Do a pattern calculation on the new antenna. In the 2D window, select Add Trace, and enter the name of the trace you just saved to show the original pattern for comparison. The distortion of the pattern is due to current induced on the outside of the feedline by the antenna -- the radiating feedline is as much a part of the antenna as the intended radiator. (Those of you enamored with with CFA, EH, or other small antenna take note!) In fact, feedline radiation can actually contribute more to the overall field than radiation from the supposed "antenna". You can see this current in the View Antenna display after doing a calculation. You'll find that very small changes in the length of the feedline wire make profound differences in the pattern. (The phenomenon is similar to what happens when you change the length of a Yagi element.)

This open ended feedline of course doesn't do a good job of representing most real feedlines, and the length was chosen to be nearly resonant. The real feedline is likely to be longer, and take a circuitous path, perhaps through the mains wiring, eventually ending at ground, and might or might not resonate. The pattern you'll actually get depends on this path and length, which are often hard to predict or quantify. But the program shows that pretty severe pattern distortion is possible for some feedline lengths, so you might or might not experience it. It also illustrates that the ground radials do an ineffective job of isolating the outside of the feedline from the antenna. I believe it's very possibly a reason people have such varying opinions about ground planes of various lengths and of J-poles -- and why people seem pretty uniformly satisfied with the AEA Isopole. It's not spectacular, but it's consistent, and independent of the feedline.

To further your education, try different ground radial angles and lengths in the model antenna, and different radiator lengths. Another fun experiment is to put a "balun" -- a resistive or reactive load of about 1000 ohms -- at the "coax" feedpoint connection (wire 6, 0% of the way from end 1), and see what that does to the current and pattern. Try

moving it, and adding a second one at various spacings. Interesting, isn't it?

The conclusion you should reach is that a description of the vertical and ground plane wires alone isn't an adequate description of the actual radiating structure -- the feedline is an integral part of the system and has to be included if you're to have any idea of how the antenna will really work.

Hopefully, this exercise will help you understand why, when you ask a question about how well a "simple" antenna will work, some of us hem and haw and answer "It depends".

They have a virtual map you can look at. There is also list of nearby hotels, but the holiday inn I mentioned is not on it for some reason. The buildings you mentioned would be about a 10 minute walk.

But it is not clear glass, it is tinted.

And, yes, I meant the window mounting not the cellular antenna (I asked that in a seperate post).

Do you have a Taurus wagon? I was hoping to find someone here who actually tried a glass mount on a Taurus. [I find it amusing how many people respond to a post without reading it. Someone actually suggested putting a mag mount on the trunk!]

You're still close enough to receive the groundwave signal, but at night
skywave signal will cause constructive and destructive interference as the
phase relationship between the twoslowly changes. I experience the same
thing in NW NJ.

I called the Holiday Inn, and checked them out on the web, and mapblast. The music dept is pretty much centered around the corner of College Road and North High street. Holiday Inn looks good, and they have rooms, but no balconies. (I called them.) The front desk fellow was very helpful, but I was not about to ask "...and how difficult would it be to get an antenna outside the room window?" :-)

It's still the front runner though, I'll ferret about Microsoft's "Streets and Trips" and a few other sources. Might even resort to calling the University itself, I'm sure they have a list (perhaps even online) of suggestions.

Thank you for all your input and advice!
Bob

One NJ station that I can't remember at the moment told me that I was the
Southern-most reception report they had (Princeton to Virginia Beach, Va).
They change from 100,000w daytime to 1,000w nighttime. Normally a powerful
Florida station overpowers their transmission.

Jack

There are four. You couldn't really have an odd number..

Metal-adhesive, adhesive-glass, glass-adhesive, adhesive-metal.

Then there's the tuner box and all that on the feedline to consider.
Not surprising that there's some significant loss in the process.

I did something similar to this as part of my Master's research, except I used a 'brute force' algorithm written in Fortran.

As the other poster suggested, you have to consider the mutual coupling. This can really mess up the pattern if ignored, except in one special case. That special case is when the array is completely symmetrical. That is each dipole 'sees' the same surroundings as all other dipoles. Since you have them in a circular arrangement, the dipoles will have to be placed radially on the circle. That is, one end of each should point towards the center of the circle.

What is happening is that the elements are coupling to each other. This introduces an additional complex impedance in addition to the self impedance of the dipoles themselves. You then have to 'dither' the phase of the driving current (for an all driven array) to get the desired pattern. In the case of an array with parasitic elements (that is, the driving current is 0.0), what is typically done is to dither the self impedance of the parasitic elements by either placing a lumped constant (inductance or capacitance) in the parasitic element, or changing the length of the parasitic element slightly. The more elements you have, the more complicated the problem becomes.

Note that the pattern for receiving will be the same as for transmitting because of reciprocity. It is usually easier to calculate the pattern for the transmit case.

Two dipoles, as you found, are always symmetrical to each other. Get yourself a copy of J. D. Kraus' "Antennas" and study the section on mutual coupling and reciprocity. The newer editions also have a section on the "Method of Moments", which is what NEC and similar programs use.

For my thesis project, I used a brute force method. Kraus gives canned formulas for the self and mutual impedances of simple antenna elements---dipoles, monopoles, etc. (actually, he only gives part of the formulas and refers you to other papers). I then wrote some complex matrix math routines in Fortran, and let it crank away. For N elements, you need an NxN matrix of complex numbers to describe the relationship between all of the elements. The self impedances will be on the diagonal, and the mutual impedances for each pairing of elements will be elsewhere in the matrix. What you do then is solve the matrix equation I=V/Z, with V being a unit matrix (for a uniformly driven array). This will give you the currents in the elements from which the pattern can be calculated. To 'dither' the currents, change the complex values in the V diagonal. For a parasitic array (I never got far enough to actually try this) all but the feed element in V is 0.0.

Fortunately, NEC does all of this for you.

By the way, a herd of bugs have 'antennae', a herd of radios have 'antennas'. (As in Kraus' Antennas).

When I use 'theory' or 'theoretically', I'm using it in the engineering context of Physics and Mathematics. Meaning the mathematical solution of the LAWs of Physics are applicable.

There are other understandings of theory: such as the district attorney's theory behind a crime; or, in science terms the next step beyond 'hypothesis'; or, the step below 'law of nature'.

The theory is understanding 'WHY' things are actually, to quote your word above. Knowledge, in engineering and science, is incomplete without the THEORY of operation or Physics.

So, I reject your hypothesis regarding Thurber's statement. It is inconsistent with science/engineering/physics.

More than likely, you are getting interference between the ground wave
and the sky wave as the strength and path of the sky wave varies with
atmospheric conditions. I don't know of a cure. I sometimes have the
same problem with the same radio tuned to WTAW, 40 miles away.

Gents,

I think the suggestion that the ground and sky wave are "fighting" each other after sunset is the answer. This would account for the "wierd" phase-shifting audio sounds that accompany the shifts in signal strength.

The links below show that I'm between the local and distant coverage pattern contours. (I'm a little east of Allentown, PA.)

http://www.radio-locator.com/cgi-bin/pat?call=WABC&service=AM&status=L&hours=D

http://www.radio-locator.com/cgi-bin/pat?call=WABC&service=AM&status=L&hours=N

Incidentally, www.radio-locator.com is a good resource for BCB Dxing.

Not a user - just a general comment.

With a proper ground plane, these antennas are effective on 10m-20m.
For portable/base operation, you can always do better on 30m-160m
with larger/longer antennas.

Bob, AD3K, made a good point that I overlooked. I had very good success with the thru-the-glass behind the rear view mirror. It even cleared the garage door.

I drive a C5 Corvette now and could not figure out where to mount the dual-bander so it is mounted on a bean bag lap top desk and ride in the passenger seat or on the hump when someone is onboard. The antenna is a small dual-band mag mount on a thin steel plate in the hatch area. It works!

Hi Dave,

Poor theory. Reflection is not loss. There are reflections galore on
a radiator that supports the Standing Wave and yet with a large enough
metal surface it is nearly 100% radiative.

As for this boundaries explanation, those "Physics types" clearly did
not have any working knowledge (experience) - about as useful as
Cecil's poorly offered Light analogies suffering from the same lack.
I further note that none of this indicts clear glass (which may have
been a semantic issue) to the tune of nearly 1dB.

Jim: I have used many different mobile antennas. They work, like any other antenna. You will make QSO's with them but they can never be very efficient even though the screwdriver marketeers say they are the most efficient mobile antennas. They will always be a very shortened vertical - that still would require an excellent ground plane to work as a portable/base antenna. They are also very cumbersome to "mount" and they pick up a lot of QRN.

I got into QRP a few years ago. I tried to make QRP QSO's using my Terlin Outbacker mobile antenna set up as a portable antenna with a rigged up ground plane of 4 radials. I had a few QSO's but poor signal reports (although I had very good success with my Outbacker in the car with 100 watts). I then made a very simple multi-band tapped dipole (W2CV Gusher) for my QRP portable operations and have never looked back. Signal reports were way up, easier to erect, MUCH more efficient and a hell of a lot cheaper!

In summary, if you already have the screwdriver go ahead and try it portable. If you are going out to buy one to be a multi-purpose mobile/portable/base antenna I would forget it and build yourself a good dipole or inverted V instead!

Hi Dave,

This is a catch-all application of "theory." The solutions are
always applicable and the casual employment of the phrase "in theory"
is thus rendered gratuitous (or rhetorical chaff) - hence the
attachment of Thurber's observation that is a sardonic reference to
the lack of any actuality. You have confirmed that his artistic prose
has as much validity as Physics.

I have operated on both an 80 meter G5RV and an 80 meter Carolina
Windom. Both performed well, but I lean towards the Carolina Windom.
The SWR on the Windom is below 3:1 on all bands and my internal tuner
has yet to have a problem matching it to any frequency. I resolved
the problem of the vertical arm by supporting at the feed point with a
fiberglass mast at 40 feet.

Greetings Cecil: I've been on the road for the past three days and am
just now catching up with my e-mail and such.

The answer to your question is that I intend to use a Van Gordon 80M
G5RV at about 40 ft. on 80/75/40 as a minimum. I'm "ambidextrous", I
motor-mouth and twitch paddles on FD so I need "bandwidth" on 80/75.
I'm building a close-spaced wires duo-band dipole for 20 & 15 which
will be hung at around 25-30 ft. If that antenna doesn't work right
I'll also have to use the G5RV on 20/15 too. In the ideal scenario
both antennas would work and I'll be able to swap antennas around for
20 & 15 depending on the pattern & propagation condx of the moment.
I'll use 8X to feed the G5RV balun which will be 8-10 foot above
ground level to keep the weight on the G5RV down

From there I'll run a length of RG-8 to the operating position. Looks
like a 75 or so foot run. I'll use my LDG-11MP ATU to tame the G5RV.
With all this coax involved the ATU won't have much "work" to do . . .

> Here's one of my rules-of-thumb for which I am infamous. :-)

> day antenna?

I've read the whole thread thru Tuesday AM, I get your point and it should work well on 80. I suspect the real advantage of your scheme is that it might be possible to cover both 80 and 75 with low overall losses which is difficult to accomplish with a fullsize dipole. Since you already have the EZNec model on hand how 'bout running a 3.50-3.85 Mhz. sweep to see if it's possible to cover that range with some single specific length of ladderline and the two-section BC variable cap? If yes I think you have a real keeper idea.

Davis RF has "RG-213 Economy" cable, whatever that is, for $0.23/foot. Good enough for Field Day.

Using 75 ohm coax is probably a good idea, I'll look into it. But I
don't want to use any small-diameter coax, the losses would be
prohibitive considering the lengths of runs I'll use.

Who's talking about all band use though? All I've heard mentioned was
80m.

I modified my G5RV yesterday to work well on all eight
> HF bands plus 6m. Field strength measurements indicated it is
> virtually identical to my 130 foot dipole on 80m.

Virtually huh....
>
> > The "average" storebought G5RV is
> > pitiful on 80m compared to the coax fed dipole.
>
> Mine is virtually equal to a resonant dipole.

Maybe close...
Your "average" storebought
> G5RV must be poorly designed -

It was.

maybe lacking a balun -

Nope, it had one. I always considered that choke/balun half the
problem...

maybe using RG-58
> coax - maybe using the wrong length of the series section transformer.

No, it was RG-8. The antenna was a common storebought version. I won't
mention names, but it's the most popular version out there.

That's pretty funny, Richard, since you are agreeing with me 100%
in this posting. Glass that allows glare loses some light in the
rearward direction (reflections). Glass that doesn't allow glare
ensures that all the light reaches the object. Unmatched RF systems
can allow reflected power to be lost from the load. Matched RF
systems ensure that all the power reaches the load (minus line
losses).

You have never said anything worthwhile that technically disagrees
with me. Your only objections are to my style (witness the above).

Shorten the series section transformer length on the G5RV to 22 feet
and you will have no trouble tuning it to a match on 75m.

Hi Richard,
absent any numbers on the loss tangent of automobile window
glass at the frequency in question, any estimate of loss is just a guess.

I feed all my antennas at a low resistance current maximum point so the
W2DU choke is indeed virtually lossless and fully functional to boot
because it is seeing its designed-for resistance. You would know that
if you took time off from your prejudice position to actually think. :-)

If it's not enough to notice on the air, doesn't your entire point
evaporate into nothingness? If no one notices whether an antenna is
resonant or not or fed with coax or open-wire line, what is the point
of your argument?

> Why? I've already done it. I don't need those numbers to help make up

That's pretty obvious and is a trait shared by the Catholic Priests who
condemned Copernicus and Galileo. I believe you will never change your
mind even if you come over to my house and see scientific evidence to the
contrary. It's a good thing human lifespans are so short or else the human
race would never make any technical progress.

Dave,

If the ground and sky waves come in at different angles, you may be able
to rotate and tilt the radio to receive one and null out the other. The
optimum angle may change with the time of day as the ionosphere changes.

Dan Jacobson wrote:
"I will put my wire to work to pull it in even better."

Fitst, you need a line-of-sight path to the desired station. Then, you need an obstruction in the response to unwanted signals. You need enough desired signal edge to capture the FM detector and to suppress noise the undesired signals might add to the mix.

An axial mode helical antenna uses a lot of wire wound into a coil which is pointed at the desired station, directly or indirectly. Diameter and coil pitch are optimized for axial gain and directivity.

If a helical coil is small in terms of wavelength, its field is maximum perpendicular to the coil axis. Such a self-resonant coil makes an omnidirectional antenna in a plane perpendicular to the coil axis.

We have a rubber ducky as an example of an omnidirectional helix which is inefficient, limited in bandwidth, but convenient for handie-talkies. Larger omnidirectional (normal-mode) helices are used by some VHF/UHF broadcasters to provide circular polarization, but Kraus says on page 173 of his 1950 edition of "Antennas":

"For normal mode the dimensions of the helix must be small compared to the wavelength, so that from band width and efficiency considerations this mode is not readily applicable in practice."

There are handie-talkie suppliers and broadcasters who don`t heed Kraus.

Best regards, Richard Harrison, KB5WZI

In the light experiments I have been talking about, the glare is the
same frequency as the laser beam, somewhere around 3x10^6 angstroms.

How many others feed theirs this way? How would I know how yours would
vary from the "usual G5RV"?

>
> If it's not enough to notice on the air, doesn't your entire point

No. That is only comparing using coax to ladder line with no other
considerations given.

If no one notices whether an antenna is
> resonant or not or fed with coax or open-wire line, what is the point
> of your argument?

Because I DO notice the difference between a coax fed dipole and either
a G5RV or the usual "windom" that is sold by "eastern state antenna co.
inc"
>
> > Why? I've already done it. I don't need those numbers to help make up

Cecil, you might have a modified G5RV that is fairly usable, but most of
the ones that are actually sold, and are in use, are lame 80m antennas
to my standards. Same for the average windom, or OCF dipole. This is

not idle speculation. I've A/B compared them at field days. I started doing this after getting stuck on G5RV's on 80m for two years in a row. "What torture..I almost pulled my hair out :(..."
The owner of one windom I tested against had no idea what he was losing until I showed him. He almost fell over at the 2-3 S unit differences we saw when flipping the switch... To answer one earlier question for you, my feedline loss at 4 mhz is .4 db for 100 ft of line at the most. Other than my ground loss, which will be the same for either types of antennas, for all practical purposes I have no loss.
You can not detect .4 db difference in the real world on 80m. And being I'll be at 3.500, it will be slightly less. And if I don't use the full 100ft, it will be even less.
When directly comparing the coax fed dipole to the commonly used "windom" that is sold by said ESA inc., the dipole was better on all signals , including just the atmospheric noise floor by a min of 2 S units. This increase is not pattern related. It's purely a difference in feeder efficiency. And that was on 40m, not 80. On 80m, it probably would have been a greater difference.
Now, Cecil, do the math. How many db difference does it take to measure 2 s units on the average radio? A lot more that .4 db, I can tell you.
On 80m, the "storebought" G5RV's we tried were the lousiest 80m antennas I've ever used without going to a hamstick on a VW. Yes, I do have high standards! I've only used full size antennas my whole 80m life... When you are running 100w, but have the performance of QRP, field day is not fun for me. You say I'm exaggerating? How many db drop will you see on the average radio's S meter if you drop 10 db? About 2 maybe ? The difference between the funky G5RV's we used, and a dipole on 80m were 2-3 S units easy. You may have modified yours to improve it, but I still don't want one. Thanks, but no thanks...
I only use full size antennas unless it's impossible. 80m on field day is ruff cdx. Noisiest time of the year, and the band is packed wall to wall. No place for compromise antennas..:)
But to each his own...Like I say, the more that use those things, the easier I'll have it. Well, except I have to strain my ears more when working those stations...:/ MK

> cap? If yes I think you have a real keeper idea.

Maybe you'll like this one. 110 ft dipole at 40 ft, fed with 110 ft of
450 ohm ladder-line and tuned with a single control dual-gang variable cap,
i.e. no conventional antenna tuner. Such an antenna system covers the entire
75-80m band with a 50 ohm SWR ranging from 1.7 at 3.5 MHz to 1.0 at 4.0 MHz,
according to EZNEC. Full band coverage at the twist of one knob? You likeie?

For a coax fed dipole, EZNEC reports an SWR=2:1 bandwidth of 170 kHz.

I found my backup all black telescoping antenna for my 2 meter handheld. I have been using one like it for 5 years without problems. I am now selling new my backup. Only $35.00 plus shipping from Canada.

Antenna good from 140 to 173 MHz.

International postal money orders only, then I can cash and ship the same time.

Dave Pitzer wrote:
"WABC (New York City) comes in poorly at night even though its xmtter is only 80 miles away."

80 miles is within groundwave range of WABC. 770 KHz should reach that far in the daylight hours as well as at night. At night, the ionosphere reconfigures allowing a reflected wave from the station to reach your receiver. While the groundwave is subject to ittle if any variation, the skywave is subject to many variations. Thats just the beginning of the problem. All U.S. stations share their assignments with other stations operating on the same frequencies. If the desired station is not interfered between its own groundwave and skywave (you are out of groundwave range) it is still likely to be interfered by other stations sharing its frequency or even interfered by adjacent channel stations. When these undesired stations fade in, they can suppress reception of the desired station by taking over the receiver`s automatic gain control circuit.

To accomodate multiple assignments on a single carrier frequency, FCC often requires new assignees to include a null toward one or more aditional existing stations, especially at night, in the new station`s radiation pattern. If the reduction in potential interference is deemed insufficient, the new station may be required to reduce power as well as switch directional patterns during nighttime hours. The new station may be the oldest station on the frequency if it has decided to relocate or make some other modification to its license terms.

So, WABC may have directional coverage of its area which it switches at nightfall and daybreak. I have an FCC book showing all the assignments but it is very out of date.

Best regards, Richard Harrison, KB5WZI

I have found that a 3/4 wl and longer vertical antenna can be quite useful during periods of "skip". Quite often these antennas will allow you to work into areas that are not so crowded. Your signal is going places others are not. This can be a good tool to have.

Mark Keith wrote:
> How many others feed theirs this way?

I don't know and don't much care. The discussion is about your
antenna Vs mine.

> How would I know how yours would vary from the "usual G5RV"?

By the length of the series section transformer. It varies from
20 ft on 10.125 MHz to 35 ft on 18.14 MHz providing less than
2:1 SWR on the coax on all HF bands - no tuner required. On 3.8 MHz
with a series section length of 23 ft, the series section feedpoint
impedance is resonant at 25+j0 ohms.

> Because I DO notice the difference between a coax fed dipole and either
> a G5RV or the usual "windom" that is sold by "eastern state antenna co.
> inc"

Theirs are not optimumized - mine is. Why don't you compare your dipole
to an Isotron so you can feel even better. :-)

> Other than my ground loss, which will be the same for either types of
> antennas, for all practical purposes I have no loss.

I can say exactly the same thing. My 50 ohm SWR is less than 2:1 without
a tuner of any kind. There's simply no places for losses to occur.

> You can not detect .4 db difference in the real world on 80m.

So if my antenna is within .4 dB of yours, it's as good as yours?
I wish I had said that. As a matter of fact, the difference between
your antenna and mine is the difference between an SWR of 1:1 and an
SWR of 2:1 on 75m. The ARRL Handbook loss chart says that is 0.12 dB
difference for 100 ft of RG-213 on 75m.

> Now, Cecil, do the math.

There it is in the paragraph above. My dipole is 102 ft long. EZNEC sez
it has a maximum gain of 6.04 dBi compared to 6.24 dBi for your dipole.
Including the 0.2 dB reduction in gain and the 0.12 dB of additional
losses in the coax for an SWR of 2:1, that's 0.32 dB modeled difference
between your dipole and my G5RV and you say one cannot detect a 0.4 dB
difference. Doesn't that shoot your own argument down?

> How many db difference does it take to measure
> 2 s units on the average radio? A lot more that .4 db, I can tell you.

I'll bet $100 that your antenna is NOT anywhere near 2 S-units better than mine on 3.8 MHz. And I'll bet my antenna is 2 S-units better than your coax fed 80m dipole on most bands between 40m and 10m where it functions as well or better than it does on 75m.

The Windom single-wire feedline radiates by design.
It would be extremely difficult to keep the OCF
feedline from radiating but a 50:300 current balun
at the feedpoint might help.

I used to live on the very fringe of an FM stations coverage area, probably outside their intended cover area. Had great succes with 4 stacked 2 element Yagis(think of old TV antennas). I and a guy down the street who had a hundred foot tower were the only people in the county who could get the station reliably. This was pretty good since this was the only FM station that serviced the area at that time.

I am putting a VHF/UHF antenna in my attic and have run coax into two different rooms in the house. I would like to be able to access the antenna, on both bands, from both rooms in the house (not at the same time, however). Is there a "remote" way I can do this, meaning without running any more wires? I have been searching for an rf triggered relay that would ground the second coax when a signal came down the first, but I can't find anything like that. A duplexer won't work because I want to be able to access both bands from both rooms. Certainly there is someone else in this hobby who has done this, but I can't find anything on the Internet about it!

ANY suggestions would be welcome.

Only suggestion I'd have is a standard antenna switch. You'll have to move
the switch to the position for whichever room you're in, but that might be
the only way.

One common approach is to run some DC voltage through the coax
to energize an antenna relay. The DC voltage is isolated from
the RF equipment using caps. A series DC relay is bypassed
for RF by a cap. A parallel DC relay is isolated from the RF
by an RF choke. The configuration is a little different
depending upon whether the antenna is a DC short or not.

285. Optimized G5RV

Newsgroup: rec.radio.amateur.antenna
Date: 2004-04-07 04:06:30 UTC
From: Cecil Moore <Cecil.A.Moore@ieee.org>
Message-ID: <40737e6b$1_7@corp.newsgroups.com>
Source record: 97186

These are actual measured values for the resonant lengths
of the series section transformer for all HF bands for
my optimized G5RV.

102' dipole, insulated wire. Ladder-line is approximately
Z0=380 ohms, VF = 0.9. Coax is RG-213

The insulation on the wire makes it electrically about 3%
longer, i.e. approximately the same as a 105' uninsulated
dipole. The ladder-line is Wireman #554, #14ga, "440 ohms",
but measures closer to 380 ohms.

Freq-MHz ladder-line length
3.8 23 ft.
7.2 35 ft.
10.125 20 ft.
14.2 29 ft.
18.14 36 ft.
21.3 27 ft.
24.95 29 ft.
28.4 38 ft.

Since my favorite bands are 40m and 17m, I keep the length
of the ladder-line at 36 feet most of the time. I rarely
work 30m so my minimum length is 23 feet. I have lengths
of ladder-line with banana plugs on one end and banana
sockets on the other end. I have one 8 ft. length, one
4 ft. length, one 2 ft. length, and one 1 ft. length so
I can achieve any length between 23 feet and 38 feet to
the nearest one foot. Of course, switches or relays could
be used instead of banana plugs.

286. slightly OT? auto AM/FM antennas & AM

Newsgroup: rec.radio.amateur.antenna
Date: 2004-04-07 05:18:53 UTC
From: The Masked Marvel <s_crook_remove_underbars_@comcast.net>
Message-ID: <1bMcc.84956$w54.501799@attbi_s01>
Source record: 97187

The common auto AM/FM antenna these days is a *roughly* 1/4 wave (for FM) 31" vertical whip. For the sake of AM reception (particularly distant cities, sky wave at night) iwould it hellp to use a longer whip, and would there be any benefit (or detriment) to FM to making "longer" = ~60" (~1/2 wave) or perhaps ~75" (~5/8 wave) vs some other random length (say 90" or even102") or does it not really matter as it is only receiving not x-mitting. I'm assuming for AM that more is better (with obvious practical limitations, probably well below the hypothetical 102" previously sited). I suppose the best thing would be to just try a 5' or 6' whip some night, but thought I'd ask.

287. quad question

I've a question for the group. When I'm drawing out my lengths of wire when making a quad, what is an accurate way of measuring it? I'm using 1.6 mil aluminum tig wire and, although the stuff usually lays pretty flat coming off the reel I want to be certain my lengths are correct. Laying a tape down next to the wire seems like it couldn't be real accurate. Any suggestions would be appreciated. Tnx, and 73.

Quite Droll, I must admit. 3 MILLION Angstroms Hmmm? This is not a
unit of frequency by the way, so I suppose some elementary instruction
is in order.

Let's see, ten billion angstroms equal 1 meter. If we do a simple
conversion we find that your laser light operates at a wavelength of
0.3 millimeters (thicker than a hair). That would seem to be more
suitable for Masers, not Lasers, and hardly light any way that you
-ahem- look at it. Let's not even suppose it is a slip of the decimal
(because it ain't). Calling it glare is icing on the cake. :-)

So, you wanna try for what's behind door number three? Only one more
round, because humor has a limited shelf life. Given both frequency
and wavelength are stumpers, how about something more remedial: "What
is the color of glare?"

Play around with the coax lengths so that the "unused" cable doesnt
present a lump to the other one in use maybe? ie multiples of half
wavelengths from the "star" connection point out.. Obviously the bands
would need to be harmonically related.

Anyone care to shoot me down on this one go right ahead!

Cheers Bob VK2YQA

Here's a relatively simple way to keep an off-center fed "Windom"
antenna feedline from radiating: Install another Windom antenna of
identical dimensions at an acute or right angle to the existing one. Tie
the long side of the second Windom to the short side of the first one,
and vice versa. Feed the thing with a balanced line, or with coax
through a balun. I don't have EZNEC (it won't run on Macs) so I don't
know what the pattern would be like, but if everything was symmetrical
the feedline ought not radiate.

291. OT: HP-4195A Network Analyzer Question

Newsgroup: rec.radio.amateur.antenna
Date: 2004-04-07 09:09:56 UTC
From: Ed Price <edprice@cox.net>
Message-ID: <DzPcc.609$Y77.270@fed1read02>
Source record: 97192

Sorry for this being a bit OT, as this bears more on antenna tools than antennas themselves.

I have been fortunate enough to acquire an HP-4195A Network Analyzer. OTOH, I did not get the HP-41951A Impedance Adapter Kit, and I would like to do some impedance measurements on 1-terminal coaxial components.

1. Does anyone know what components are in the adapter kit? (I assume that there may be a splitter and a directional coupler.)

2. Can the 4195A's front panel terminals (S1, R1 & T1) be connected to generic splitters and couplers to allow impedance testing without the 41951A kit?

TIA!

Ed

Cec,

Behaviour of your feedline lengths for the various bands is interesting. But it's likely optimum lengths for individual bands for anyone else will belong to a different set. Your list is a guide just to the sort of thing to expect.

Zo of the feedline has just as much influence on its impedance transformation properties as does its length. Your measured Zo of 380 ohms will have an effect considerably different from the nominal ladderline value of 450 ohms or other impedances which other people may have.

There are, of course, other reasons for variability in optimum feedline lengths. I don't think G5RV ever specified the impedance of his balanced line - only that it should be 1/2-wavelength long around 14.15 MHz. Even 50-ohm coax would be OK on the 20m band. It's a fair match at either end.

Hi, all concerned:

Is this the balun problem?

For openers, a 40-meter half-wave dipole with trees and 3 dogbone
insulators, center-fed directly across the center insulator with 33 feet of
RG-59/U coax, nothing special,

```
TREE--o///o--------------o///o--------------o///o--TREE
| |
coax
feeder
drooping
down
33
feet
here
to
the
shack
```

you know, like that ASCII sortagraphic. Like the one I put up in 1957 or
1958.

The thing has voltage loops at all ends, including the shack-end of the
coax-braid, correct?

73, Dave, N3HE

Why isn't an Angstrom a measure of wavelength?? You yourself simply translated it into a parameter of your choice as 0.3 mm.

My 4.0 MHz antenna is 120 feet. Is the unit of feet not a measure of wavelength? Could I not use a furlong as a unit of length?

I offer that ANY unit of length is acceptable in expressing wavelength.

Your problem is selective fading. You are probably using an ordinary
AM receiver. When the selective "notch" hits the carrier it gets very
weak and the automatic volume control turns up the RF-amplification.
But at the same time the sidebands are not nulled out to the same
degree. So you get a loud distorted audio signal resulting from
relatively strong sidebands and a very weak carrier.

If you couldn get a receiver with single sideband reception or - even
better - fase-locked "sync" reception you would get better sound. You
would still get some distortion but it would be of a much less
malignant (linear) kind. I would thnk that this is a more realistic
solution than trying to null out the different signal path with some
sort of sophisticated antenna. I use a Sony "sync" shortwave receiver
myself for listening to eg. BBC with good result.

Hi Paul,
The first step is to straighten the wire. Depending on diameter, you may be
able to anchor one end to a fixed object (pipe, fence post etc) and tie a
rod to the other end and stretch it. For bigger copper I have tied it to the
bumper hitch and moved the car forward slightly. The end result is a
perfectly straight length of wire. Now, it can be laid flat and parallel
againsta a tape. Mark off the overall length and the corners w/ a magic
marker.

I have a CCRadio and the Select-A-Tenna receiving loop that the same people sell. The loop works extremely well on weak AM signals, but only if that frequency is clear of other nearby stations. **If** the frequency is clear, and there is just the barest signal from the station you want to hear, the loop will really pull it up and make it loud.

You can also homebrew these loops, and you might find plans on the internet somewhere.

You are lucky in that your receiver has an AM antenna terminal, so you can attach an outside wire. I'd certainly try that -- wouldn't cost much at all.

Sounds good. What I would do is this: say you have radios A and B. Run 12V up the coax when radio B is turned on. Arrange the relay so that the antenna feeds radio A when there is no DC on the line. Strictly speaking, you should use a coaxial relay, but a cheap SPDT relay will usually work. I would put the relay within about an inch or so of the antenna feedpoint.

302. Receive antenna question..

Newsgroup: rec.radio.amateur.antenna
Date: 2004-04-07 14:16:19 UTC
From: fred@albert.usd253.org
Message-ID: <4a2da7a9.0404070616.230ab728@posting.google.com>
Source record: 97202

I am wondering if this will worki¿½

This is for receive onlyi¿½. I have a mag mount antenna that I have trimmed to around 19" for around 155 MHz (1/4 wave), I was wondering about adding a 6.5" antenna next to it for UHF.

The antenna is screwed to the mag base on a 1/4 20 stud. My idea is to take a 2 inch piece of flat steel and drill a 1/4 inch hole to mount under the antenna. Then I will attach my 6.5" antenna..

```
|
| <-- 19"
|
| |
| | <-- 6.5"
|_|
|
|
|
| <-- Coax
|
|
```

My other question has to do with grounding. I used my VOM to check and see it the outer braid of the coax goes anywhere. I thought it might ground to the magnet but this is not the case. The center of the coax goes to the 1/4" stud on the mag mount but the outer braid seems to not go anywhere.. is this right?

Thanks!

Fred

Richard Clark wrote:
> Let's see, ten billion angstroms equal 1 meter. If we do a simple
> conversion we find that your laser light operates at a wavelength of
> 0.3 millimeters (thicker than a hair).

Yep, I misread the units from a chart in Reference Data for Radio Engineers. I accidentally picked a point in the low infrared region. Macular Degeneration is playing havoc with my eyesight. But, FYI, infrared lasers are readily available.

And EM is still EM no matter what the frequency. If it will make you happy, let's discuss the familiar helium-neon laser whose wavelength is 632.8 nm. Incidentally, you said anstroms are not a measure of frequency. FYI, neither is wavelength, your preferred units. :-)

It really doesn't matter what EM frequency we discuss. We can cause reflections (glare) at any frequency. But the experiment I previously discussed used a coherent laser light source normal to the plane of the thin-film. The two problems solved in the following diagrams are virtually identical (where 'n' is the index of refraction).

100w laser-----air------|----1/4WL thin-film----|--flat black
n=1.0 n=1.225 n=1.5

100w XMTR--50 ohm coax--|--1/4WL 61.2 ohm coax--|--75 ohm load

The physical reflection coefficient magnitude is the same in both cases, ~0.1. If one understands how the thin-film eliminates reflections (glare) then one understands how the match point eliminates reflections an RF transmission line. How the thin-film works is explained at:

http://www.mellesgriot.com/products/optics/oc_2_1.htm

Incidentally, J. C. Slater, author of _Microwave_Transmission_, understood all this stuff way back in 1942. Here's a couple of quotes: "Thus a light wave incident on a discontinuity between two media, as a surface of separation of air and glass, is reflected. If the surfaces are separated by a quarter wave film of material whose index of refraction is the geometric mean of the indexes of the two media, however, the reflection can be eliminated;"

And for RF transmission lines: "We can get a better understanding of this device by considering reflections at discontinuities. This method is useful in considering any impedance-matching device, and we shall think of it first in connection with the ordinary quarter wave transformer. The object of this transformer is to eliminate the reflection that would be present if the impedance Z1 were

connected directly to Zt. The method of eliminating reflections is based on the INTERFERENCE between waves. Two waves half a wavelength apart are in opposite phases, and the sum of them, if their amplitudes are numerically equal, is zero. The fundamental principle behind the elimination of reflections is then to have each reflected wave CANCELED by another wave of equal amplitude and opposite phase. In order that this second wave may have traveled half a wavelength farther than the first, it is OBVIOUS that it must have gone a quarter wavelength farther up the line, and correspondingly a quarter of a wavelength back, before it meets the original reflected wave. In other words, two discontinuities in characteristic impedance, of such magnitude as to give equal amplitudes of reflected waves and spaced a quarter of a wavelength apart, will give no NET reflection and hence will not introduce reflections into the line."

Mr. Slater goes on to provide an example like mine above. So my question is: If all this stuff was known and published as far back as 1942, why do you, Richard, reject it in 2004, 62 years later?

It's even worse than that, Dave. Richard said Angstroms are not a
measure of *FREQUENCY* and then turned around and used wavelength
which is also NOT a measure of frequency. One wonders why his
non-frequency units are superior to mine. :-)

Hi Paul -

The Hy-Gain AV620 and AV640 models have good reputations for this type of antenna.

If you have a little bigger budget, can put in a full radial system, and don't mind running a control cable, the SteppIR verticals should perform extremely well.

I have a Sommer T-25, which is OK on 40, 20, 17, and 12, excellent on 30 and 10, but poor on 15. I normally use my dipoles on all bands except 10, where the Sommer performs best.

I suggest you check the eHam.net Reviews on antennas. It also provides links to manufacturers sites, where you can (sometimes) get additional information.

He said frequency and then turned around and used wavelength. Wavelength
is also NOT a unit of frequency. His "elementary instruction" violated
his own objection and was thus inconsistent.

Yep, my point was that anyone with an MFJ-259B, like mine, can optimize
their own G5RV for true all-HF-band operation especially if they have
a built in autotuner like my IC-756PRO. One complaint I hear is that
the built in autotuners won't tune a G5RV on all HF bands. Well, here's
one way to solve that problem.

Hi,

for hf antenna easier to let it hang down and for vhf you have element
pointing up
but the horizontal portion cancels out. Either way end fed.

www.cebik.com has large section on half square at hf and vhf.

Hello OM,

In the Navy my students learned at every level of instruction to:
RTMFQ!
That question was:
>>name what frequency glare is.

Now and then a student would come through who would respond
"the frequency is such and such meters"
as they passed out into the fleet as a deck-ape.

I am new the world of radio waves, but I am trying to find out if I can buy a device which will tell me how strong the radio waves are coming from a large antenna? This is assuming that I am standing within 10 meters.

I know that a frequency counter tells me which frequencies are being transmitted. But what tells me how strong they are? Any idea who sells them?

Any ideas?
Thanks, Meeker

Thanx Roger,

I am not such the pedant as to demand frequency however. But for this particular exercise 0.3mm is invisible to everyone, as is 0.03mm, 0.003mm, or 0.0003mm. The revealing point is that there is no wavelength with a significant three that is visible!

Such is my style to reveal the paucity of experience. As for this mystery frequency/wavelength/color, I will offer a clue, very very short so as to not confuse (but it will) in a follow up post to this as an attempt to mine the humor beyond its expiration date :-)

Hi Butch,

There is no gain in any antenna. An isotropic source represents a
reference. One may choose any other antenna, a dipole being a common
basis of comparison.

In this sense of comparison, gain as a term then becomes an indicator
of differences between the subject at hand and the reference.

If there was one, it wouldn't have any.
That's part of the definition, since it radiates in all directions equally.
You get gain by adding directivity.

Paul,
Accuracy is 'relative'. For HF, 'close' is 'good enough'
when
measuring the length of your antenna elements, since any formula
derived length is only a 'ball park' figure to start with. For
VHF/UHF element lengths that 'ball park' figure has to be
measured
more carefully, but it's still just a 'ball park' length. To
fine
tune an antenna's length requires 'checking'n'chopping' till you
get it exactly where you want it. Horse shoes and handgrenades
ain't the only things where 'close' counts...
'Doc

'M.M.',
The length of the antenna isn't going to make a lot of
difference, but it's height will, sort of. Extending the
length of your car's antenna isn't the answer (no matter
if it's for AM or FM).
If you could raise the height of the antenna to 100 or
more feet, you'd certainly hear more stations because you
will have extended the antenna's 'horizon' further. 'Course,
that 100 feet height would make driving down the highway
kinda difficult...
There are no 'magic' fixes to extent radio reception in
the average car's AM/FM radio. 'Practical' isn't the same
as what would be 'best', and your 'better-half' probably
wouldn't put up with it anyway...
'Doc

If you have improved yours, I'm glad. You may well have a decent
antenna. But you need to spread the word, because most other's that
are unmodified are still gonna be lame radiators. What proposal do you
offer to correct the feedline deficiencies of the average storebought
windom, or OCF dipole on 40 and 80m? They need your help too. If you
all get your heads together, you might be able give me some rf
competition this year... :) MK

> That's part of the definition, since it radiates in all directions equally.
> You get gain by adding directivity.

Those statements illustrate several misconceptions about gain and directivity.

The first is that gain is an absolute figure -- that a particular antenna, like an isotropic radiator, has an immutable, single, value of gain. That isn't true. Gain is always a relative term. It's the ratio of two numbers. One of those two numbers is the field strength from the antenna, the other is the field strength from the reference antenna in the same direction. You can get just about any gain you want from an antenna simply by changing the reference. For example, a dipole in free space has 0 dB gain relative to a dipole in free space in its most favored direction. It also has 2.15 dB gain relative to an isotropic source, something like -6 dB gain relative to a 3 element Yagi in free space, and about -5 dB relative to the most favorable direction of a dipole mounted over ground. So the same dipole has a gain of 0, 2.15, -5, and -6 dB in its most favored direction. It also has an infinite number of other gains. This hasn't been lost on antenna manufacturers, who are often very creative in their choice of reference. People who believe that gain is an absoulte value independent of the reference are their rightful prey.

The second misconception is that the gain of an antenna is a single value, even if the reference is given. The gain of a dipole in free space varies from 2.15 dBi (dB relative to an isotropic source) to -infinity, depending on the direction. It makes sense to look only at the maximum gain if you're able to rotate or construct the antenna so you can point the most favored direction at the station you want to communicate with. Otherwise, it's a meaningless number. Who cares how strong a signal the antenna radiates straight up (unless you're using it for NVIS propagation) or at some azimuth or elevation angle other than the one you're using to communicate? An extended double Zepp (EDZ) has gain over a dipole -- but only over a rather narrow range of angles. At all other angles, the gain is negative. If the station you're working is at one of those other angles, you're better off with a dipole -- because

it has more gain than the EDZ at that angle. And if you're equally likely to work stations in any direction, you'd do better with a dipole most of the time. Whenever the antennas have different pattern shapes, their gains will be different in different directions when compared to the same reference or to each other.

The third misconception is that the gain and the directivity are the same. If two antennas are equally efficient, then the one with the greater directivity will have the greatest gain (by the amount of the directivity) in its most favored direction. But there's more to gain than just directivity, and that added something is efficiency. Two antennas can have equal directivities but different gains relative to the same reference. For example, a free space dipole with a 73 ohm resistor at the feedpoint will have a gain of -3dB -- in all directions -- compared to one without the resistor, even though both have the same directivity. (Here, I've used the antenna without the resistor as a reference. I could also use the other as a reference and say that the antenna without the resistor has a gain of 3 dB relative to the one having it. Or I could have said that the one without the resistor has a gain of 2.15 dB relative to isotropic in its most favored direction, and the one with the resistor has a gain of -0.85 dB relative to the same reference. All are equally valid.) A Beverage antenna typically has high directivity but considerably lower gain than antennas with lower directivity such as a Yagi of a few elements, or even a dipole. An inefficient antenna with a perfectly isotropic pattern has a negative gain (in dB) in all directions relative to the theoretical, perfectly efficient isotropic source.

There is one unambigous way of stating gain without describing the reference, and that's to give the gain in dBi. If you do this, it's understood that the gain is relative to a 100% efficient isotropic source. Of course, you still have to say whether that's in the antenna's most favored direction or in some other direction unless it's obvious from the context. If you don't use the isotropic reference, you need to clearly describe the reference, or any gain figure you quote is meaningless. "dBd" is a popular term among hams, and a windfall for less scrupulous antenna manufacturers. Often defined as gain relative to a dipole in free space, it's just as often defined, understood, or misunderstood to mean gain relative to a dipole over ground at the same height as the test antenna. The 5 or so dB difference between these two meanings of the same catchy term offers ample opportunity to confuse the consumer and make an antenna look much better than it really is. So be very wary if you see this term, and don't make any assumptions about what it might mean.

There you go again, contradicting Balanas, Kraus, Jasik, Terman, et al. From Balanis: "Absolute gain of an antenna (in a given direction) is defined as "the ratio of the intensity, in a given direction, to the intensity that would be obtained if the power accepted by the antenna were radiated isotropically."

This is the exact definition of antenna gain given in the IEEE Dictionary.

Balanis goes on to give ten equations for gain in the next two pages.

It is called a Field Strength Meter. There are two basic types.
Calibrated, which gives you the actual field strength in Volts/Meter or
Watts/SquareMeter, and uncalibrated, which gives you the relative field
strength, relative to where ever you had the knob set the last time. The
uncalibrated kind are good for comparing two antennas or adjusting a single
antenna for maximum signal.

Do a web search for Field Strength Meter and you will be sure to find a
bunch. Google lists 5530 hits.

The calibrated kind are usually quite expensive.

It's a well-designed G5RV, the best I know of. You said you dipole would
beat "any" G5RV by S-units.

> If you have improved yours, I'm glad. You may well have a decent
> antenna. But you need to spread the word, because most other's that
> are unmodified are still gonna be lame radiators.

I posted my actual measurements yesterday. To optimize a G5RV for 75m,
make the series section transformer 25 feet long and put a 1000 pf
capacitor in parallel at the coax/open-wire junction. The beauty is
that you still have the framework for an all-HF-band antenna. Take
away the cap and extend the series section to 36 feet and you have
a G5RV optimized for 40m and 17m, my favorite bands. It takes about
two minutes for me to make that change but it could be automated.

> What proposal do you
> offer to correct the feedline deficiencies of the average storebought
> windom, or OCF dipole on 40 and 80m?

The original windom, powered by a tube transmitter with a pi-net matching
network, was a pretty good antenna. For today's "Windoms", I would advise

everyone to feed OCF's with open-wire line, equipped with an excellent choke, at a current maximum point, using whatever ratio balun is appropriate. I had an OCF in college, fed with open-wire line, powered by a Heathkit with a pi-net tuning network. It's feedpoint impedance on the harmonically related bands was in the neighborhood of 300 ohms. Matching a tube final to 300 ohms through a pi-net tuner is pretty much a no-brainer and relatively lossless.

The thing has voltage loops at all ends, including the shack-end of the
>coax-braid, correct?

Well, it would seem to have voltage loops at each end of the dipole. If the antenna feedpoint impedance is 75 ohms non reactive and the surge impedance of the coax is 75 ohms, then you should see 75 ohms at the shack. No voltage loop. Do you need a balun? I would think that if everything were perfectly balanced, and you had a perfect 75 ohm match at the shack, then no balun needed. A perfect match at the shack indicates no current on the outer braid of the coax because of imbalance, or rf pickup. Everything is radiated at the antenna. That is one of my goals, along with the direction of radiation. If changing the length of coax changes the impedance at the shack, that indicates feedline radiation.

> To send e-mail, use "ca" instead of "caz".

I modeled the above with EZNEC using two perpendicular one-half wave elements one-quarter wave above
ground at 7.2 Mhz. Each half-wave was divided at a point one-sixth wave from the end The short end
on each side of the feedpoint was connected to the long end of the perpendicular wire. The source
was placed on a 2 inch wire between the two short-long pairs. I included a wire to ground from one
side of the feed point to show shield current.

At 7.2 Mhz, the feedpoint impedance was 59 - j157. I didn't attempt any element adjustments to make
it resonant. The far-field pattern approaches omni-directional with 7.7 dbi at an elevation of 60
deg. The wire from feedpoint to ground shows very little current.

At 14.3 Mhz, the feedpoint impedance is 37 + j138. The far-field pattern is bi-directional with 11
dbi at an elevaton of 30 deg. The wire from feedpoint to ground shows current similar to the
element current.

So it appears to me that the feedline may not radiate on some frequency but definitely will radiate
on others.

In the immediate vicinity of a transmitting antenna, there are generally electric and magnetic fields which are not "radio waves" (electromagnetic fields). If you really want to know the "radio wave" (electromagnetic field) strength, you should measure it far enough away from the antenna. Do a Google search for "antenna near field" for a whole mess of references. The first that popped up for looks like a good start: https://ewhdbks.mugu.navy.mil/ANTNRFLD.HTM. After you have an understanding about near and far fields, have a look at things like http://www.scott-inc.com/html/nist.htm, or other pages you can find with a search for "NIST standard antenna." You'll also get a lot of references from an "electromagnetic field measurement" search, but a lot of them will be for places that will do the measurement for you, and a lot of the rest will refer to NIST work. The essence is to measure the voltage developed across a standard antenna placed in the electromagnetic field you wish to measure. You can either build or buy a standard antenna for the measurements.

If you only care about relative measurements, like "did it get stronger after I did this or that," then you can use any old antenna and simple detector and meter arrangement and just look for changes.

Cheers,
Tom

I think it would *still* probably slightly beat your antenna. I'm fairly
certain even your G5RV will not be a complete equal to my coax fed
dipole. But that is my opinion, and it's not worth 100 more posts to
argue about it. It's common knowledge a coax fed dipole on the low bands
can be in the range of 95% +- efficient as far as the whole system. You
claim to be in that neighborhood, and may well be. But I'd have to see
it to totally believe you would be effectively equal. I bet on the air,
you would still see a slight difference. Might be small, but I bet it
would be there. I still don't like the coax/choke/ladderline combo
despite your claims that they are totally lossless. If you were to run
ladder line the whole way, I'd have much less trouble believing you.

>
> > Yes. IF...But I will still prefer the coax fed dipole.

No I didn't . I've clearly agreed with improvements it could be a lot
closer. "As in your's" You reposted it below yourself... But yes, I
will repeat...My dipoles will handily beat *most* G5RV's on 80m.
Probably even yours by a slight amount.

I guess thats great if you are worried about all bands...I'm more
worried about brute performance on the band I'd be actually using at
field day...We aren't discussing home antennas...I don't think they even
do 17m on FD...
>
> > What proposal do you

I'll let all those tube rig users at field day in on this information.
But most I see use solid state rigs...But I'll pass this on anyway...
They most all are using the tuners, so only a feedline change will be
needed. I bet they still will have inferior radiating devices in the end
though.....:(
Myself, I think multiband 102 ft dipoles should be fed only with ladder
line...Why are you not using your cut ladder line method for G5RV's?
Enquiring minds wanna know...:/ Why would someone prefer a G5RV over
your normal 80m size all band ladder line fed antenna for FD on 80m?
Enquiring minds wanna know that too...:}
Actually, I could care less what people use at field day, I just wonder
why many I see seem to prefer semi-dummy loads when they have the room
to avoid it...It's gotten to where full size efficient antennas seem to
be the exception, not the norm. And most have never heard of you, or
your modifications, and many are not really into antennas that much,
except to know they have to string them up somewhere. So they just

semi-dummy load along, blissfully unaware it would seem...They don't know what they miss, because many never try one, thinking they need all those extra bands...A regular coax fed dipole is not fancy or gimmicky enough I guess... Oh well..G5RV onwards folks! MK

My Physics books indicate that wavelengths greater than 610 nm are 'red'.

To the original 'Glare' question:

Glare is a scattered reflection of source light. It's wavelength/color is a function of the color temperature of the source, or the color spectrum of the source as in solar, and the absorption coefficient[s] of the reflecting material[s] at the wavelength or over the spectrum of the source.

So, in general terms, the color of glare has the primary color of the source and a second component based on the absorption cross section [color] of the glare producing material.

In simple terms, glare contains two or more spectral responses that may be line sources, or spectral sources and line reflections from 'pure' material or spectral sources from compound materials.

Potentially, glare can contain the entire visible spectrum. [400 nm to approximately 700 nm]

At RF, HF, VHF, UHF, SHF, etc. the parallel to glare is scattering from a reflective surface where the line spectral response is the single frequency. And reflection of spectral powwer density is scattered background noise; like from BPL :-)

You will have an imbalance with the antenna as described, not pictured.

The inner surface of the braid and the center conductor contains the rf
from your transmitter. The portion of the wire connected to the braid
does NOT get the same amount of power [current] as the portion connected
to the braid. So, one side of the antenna radiates more power than the
other. The coupled signal onto the external portion of the braid does
NOT cancel and you have RF on your coax.

Solution: Balun!

<david.shrader@comcast.net> wrote:
>Glare is a scattered reflection of source light.

Hi Dave,

This is a definition by example, and as such is a weak one because it can be shown that other example definitions neutralize it.

Glare is first and foremost a subjective interpretation. In other words it has to be observed by a human and described as distinct from other sources of light. As such, the common vernacular easily allows the expression of "the glare of the noon day sun" when in fact there are no reflections being observed. Stage lights are said "to glare," again without any notion of a specular surface. In fact, the vernacular allows that a steady stare with malice is a "glare."

The point of the matter is that to say something is anti-glare; and for the specific notion of what glare means having to be ferreted out; then this necessarily throws the original statement into doubt and confusion (which makes it perfectly suitable for internet posting :-)

It is absurd to call an application anti-glare without commenting on the wavelength of the source, as you point out. To this point it appears that it only works for red (and no other color). This is, of course, true, and simultaneously irrelevant to common applications.

I already admitted it was a mistake caused by macular degeneration.
Guess you would rather I be completely blind, eh? I thought I was reading
the frequency of visible red. I don't carry such things around in my
head. Hardly any amateur radio operator does.

"Glare wavelength" is just a logical diversion from your lack of knowledge
about interference. The wavelength of glare matters not one iota to the core
of the technical discussion that you are trying to avoid at all costs. Why
do you disagree with J. C. Slater who understood interference probably
before you ever wet your diapers?

Yep, and "glare" from the laser experiment I proposed is limited to a
single laser frequency. That Richard C. would ask, what is the frequency
of the glare from a single frequency laser beam, just shows an extreme
amount of ignorance.

Too bad you didn't know that the glare frequency from a red laser is
the same frequency as the laser. If you had known that, we could have
saved a lot of bandwidth because you never would have asked the question
and I wouldn't have made the visual mistake when I read the frequency chart.

100% relevant to comparisons to single frequency RF transmitters.
Red lasers are single frequency. Therefore, they are appropriate
vehicles for comparison to single frequency amateur radio RF
transmitters. All your pissing, moaning, and hand-waving won't
change that fact. Ham transmitters are hardly anything like a
light bulb, the diversion that you are attempting to insert. Ham
transmitters are a lot like lasers, the subject you are trying to
avoid at all costs.

If it is a passive device, which it is, there is no gain.

There is vector addition and subtraction of EXH fields to form a beam.
That's math!!

However, I don't know of any Yagi, Quad, 4-square, that with 100 watts
into the antenna and 100 watts radiated, assuming 100% efficiency, has
any gain!! It has directivity!!

Now, my Ameritron 80B takes 65 watts in and delivers 900 watts out.
That's gain! It converts 1400 watts plate power to 900 watts rf [key
down conditions].

<david.shrader@comcast.net> wrote:
>My Physics books indicate that wavelengths greater than 610 nm are 'red'.

Hi Dave,

Last touch on this point of experience. Probably very, very few
scientists and even fewer engineers would subscribe to this. It is
fine for a commonplace description useful for discussion in cocktail
parties, or tailgate parties (why they would want to know this rather
inspecific specific is another issue).

I dare say any commercial application would characterize 610 nm as
either yellow or orange. However, this is again a problem of human
perception - just like calling sunlight yellow (most photographers
would beg to differ) or calling it white (the rest of the
photographers would beg to differ). In one word: Subjective.

So, to the nature of glare, and its frequency and to the ACTUAL
purpose of anti-glare glass
it supposedly suppresses the reflection of rare gas light by
covering sensitive exhibition photographs:
Ar - Argon vapor
Na - Sodium vapor
and a host of other mixes, none of which are commonly red ;-)

When was the last time you visited any photographic art galleries that
were illuminated with Neon? Anti-glare is just a marketing pitch
anyway, how many photos are illuminated under any wavelength specific
source? The truth of the matter is that all general purpose lighting
is broad banded and negates any promise of "anti-glare."

>>one way to solve that problem.
>
> I'm guessing you have no coax here? Just ladderline from antenna to
> rig?

No, no, no! In every respect, my antenna is a G5RV using RG-213 from the ladder-line series section transformer to the hamshack. If someone has a G5RV, he can modify it to work virtually perfectly on all HF bands, including the coax feed. Everything about the G5RV remains the same except the ladder-line length is modified, and in the case of 75m, a parallel cap is installed. These modifications are super easy.

As an example of virtual perfection on 3.8 MHz, the ladder-line is made 25 feet long and a 1000 pf parallel cap is installed at the ladder-line to coax junction. The impedance at that junction is very close to 50 ohms resistive so coax is acceptable. Exactly the same techniques can be applied to all the other HF bands, most of which require no parallel impedance of any kind.

I will publish the details for each band as I work them out. But this antenna of mine is a G5RV in all respects. It is a 102 ft dipole fed with 20-36 feet of ladder-line. The SWR on 3.8 MHz is high so the 1000 pf capacitor is needed to rotate to 50 ohms through the 1/50 conductance circle.

For the uninitiated, if you have a 25+j25 impedance, you can cause that impedance to twist to 50+j0 ohms by installing a parallel capacitor. On 75m, that capacitance value is about 700 pf. My antenna works best with a parallel 1000 pf capacitance on 3.8 MHz.

All G5RVs can be modified to work perfectly on all HF bands. The G5RV has gotten a bad rap because no one has published those modifications. But it is actually an excellent all-HF-band antenna. It takes me about two minutes to change bands from 75m to 40/17m. And, for the lazy, that change could easily be automated.

Hey Dave, crack out your trusty IEEE Dictionary and reference their
definition of gain. It's not the same as yours. According to the IEEE
and Balanis, the only difference between directivity and gain is the
antenna efficiency. A 100% efficient antenna would have gain equal to
directivity. Sorry, that's the definition.

But you, yourself, have admitted that the difference is negligible. It
is indeed around 0.4 dB according to all my calculations. And the reward
is that one gets eight antennas for the price of one, i.e. 8 HF band coverage.
If you were feeding your 75m dipole with ladder-line, I wouldn't have nearly
as strong an argument.

> Myself, I think multiband 102 ft dipoles should be fed only with ladder
> line...Why are you not using your cut ladder line method for G5RV's?
> Enquiring minds wanna know...:/

Because it is so easy to achieve nearly a 50+j0 ohm feedpoint impedance at
the series section to coax junction. It is actually relatively difficult
to achieve nearly a 50+j0 ohm impedance using my variable length ladder-
line scheme at the operating position with a 102 foot dipole. But it is
easy with a 130 foot dipole. I simply got tired of the bad rap you and
others were giving G5RVs and chopped my 130 foot dipole to 102 feet. Now
you have to suffer the consequences. :-) What I am trying to demonstrate
is how series matching section transformers work not just at 1/4WL and
1/2WL but at many other lengths.

> Why would someone prefer a G5RV over
> your normal 80m size all band ladder line fed antenna for FD on 80m?
> Enquiring minds wanna know that too...:}

Many hams cannot string a 130 foot dipole but can manage a 102 foot dipole.
I've pushed the 130 foot dipole for years. Now I'm pushing the 102 foot
dipole. Sorry if that is politically incorrect. I simply cannot stand by
and allow new old wives' tales to take over ham radio.

> i.e. no conventional antenna tuner.

. . . OK but 110 feet of feedline to an antenna at 40 feet is a whole
lot of feedline to deal with under normal installation condx. At least
around here in suburbia.

> Such an antenna system covers the entire
> 75-80m band with a 50 ohm SWR ranging from 1.7 at 3.5 MHz to 1.0 at 4.0 MHz,
> according to EZNEC. Full band coverage at the twist of one knob? You likeie?

Sure do, could be extremely useful, I've moved it into my "idea book".
It's an easily tunable 80/75 variation on the similar antennas in your
website.

> For a coax fed dipole, EZNEC reports an SWR=2:1 bandwidth of 170 kHz.

That's roughly what I get with with Nec-Win-Plus. If I make the dipole
131 feet long I get the following SWRs:

3.50 Mhz = 3.2
3.65 Mhz = 1.5 (curve min point)
3.80 Mhz = 3.5
4.00 Mhz = 4.7

So it's not possible to get much bandwidth across 80/75 with a simple
dipole without an ATU no matter how you diddle it. Then you're down to
a low-loss tuning scheme like you've come up with which in this case
is a complete no-brainer. IF one can figure out to what to do with all
the excess feedline without messing it up.

Depending on how hard you "bump" it you'll also strain harden the wire
to some extent which improves it's strength and reduces it's tendency
to stretch in service. Particularly if it's all-copper wire.

Hey, but not for field day. Whoever heard of a "field" with no room for
110 feet of feedline?

> IF one can figure out to what to do with all
> the excess feedline without messing it up.

It can be coiled into a big helix as long as the adjacent coils are
a couple of feet apart. You can run an insulated rope to the antenna
feedpoint and coil the ladder-line on the rope with the coils tiewrapped
a couple of feet apart. At the least you would have a conversation piece
to discuss over 807s (the best part of field day. :-) A photo of it would
probably make it into QST since it looks somewhat like a slinky. ;-)

Tnx for all the responses. As I mentioned, the wire I'm using is 1.6 mill. diameter aluminum mig wire. This is a 2 element, 10 meter antenna. This afternoon I tied one end to a tree right next to the end of a 50' tape and ran out the both of them to the desired length and snipped the wire. I repeated this for the other and commenced to tying this rascal up.

Isn't there a 10-10 CW sprint coming up sometime soon? Looking forward to putting it through its paces. Tnx agin for the responses.

Thats only between mine and yours, and IF your's works as advertised. In the real world, I have never seen this happen yet. Heck, in theory, there should be no real difference in using a coax fed 80m dipole, and a 80 dipole fed with my tuner, and ladder line. Using the bare min inductance of course... In theory, there should not be enough difference to notice. In theory...So far in the real world, it hasn't worked that way for me. I saw a noticable difference. Probably about 5 db's worth if using strong signals in the upper part of an S meters range. Now, in that case, the loss was quite livable for just average use. It wasn't near as bad the the G5RV's we used. The feedline loss in THOSE PARTICULAR G5RV's was quite large on 80m. I actually had quite a bit of trouble even contacting many other stations. Led to hair loss...

> you have to suffer the consequences. :-)

How's that? If you change it, it's not quite the usual "g5rv" that I complain about. It's a different antenna. Actually, I think calling it a G5RV is silly unless it's used as a 20m monoband antenna as was originally designed. The G5RV's I saw were really bad on 80m. It's not just something I'm making up. I was so disgusted with the things after

the 2nd FD, I refused to ever use one again. And I haven't. I bring my own wire and coax just to make sure I don't get stuck on one. And I wasn't the only one complaining either...
I won't be suffering with a system efficiency in the mid 90's...

What I am trying to demonstrate
> is how series matching section transformers work not just at 1/4WL and
> 1/2WL but at many other lengths.

Well, thats fine. But I'm trying to tell everyone to live a little! Go with gusto! You only spin once! Use a full size efficient, resonant, antenna if you want manly 80m FD results and have the room for it. I suppose being resonant should not really be an issue, but in this case it is. It's hard to beat a 50 ohm antenna , fed with 50 ohm line, by a 50 ohm radio. To me, that is the "perfect" setup. It just so happens a 1/2 wave dipole lets all this fall into place. And it just happens that a 1/2 wave dipole has a near optimum pattern for the usual FD type operation on 80m. To me, anything else is like sticking a finger on the perfect painting , and smearing it around before it's dry.. :/
I guess this is what led me to question your choice of the perfect FD antenna. 80m, being the band of real issue.

>
> > Why would someone prefer a G5RV over
> > your normal 80m size all band ladder line fed antenna for FD on 80m?
> > Enquiring minds wanna know that too...:}
>
> Many hams cannot string a 130 foot dipole but can manage a 102 foot dipole.

At field day? A lousy 15 more ft a side? Man, they need to find a better place for field day...
Thats sad....:(
Here's where we were last year...http://bvarc.freeshell.org/images/FD2003/index.html
No trouble stringing up a real dipole around that place..."It's a fire training facility in Richmond Tx."
Note my portable tower and beam I bring on a motorcycle trailer. Thats why I fear you not on the upper bands....:) BTW...My tower was the lowest, but the highest scoring...Due mainly to superior operating skills though...No, not by me...:/ I didn't use it...Blame N5XZ...
There are other beams also... If I were to FD by myself, I'd drive down to the beach and operate off the salt water.
Probably could just sit in the truck and use the mobile setup...
Wouldn't need to get out and do any actual work... :/

> I've pushed the 130 foot dipole for years. Now I'm pushing the 102 foot
> dipole. Sorry if that is politically incorrect. I simply cannot stand by
> and allow new old wives' tales to take over ham radio.

I like your all ladder line design better from an efficiency standpoint...But claiming a coax fed dipole is nearly invincable as far as wire ant/dipole efficiency's go, is hardly a wives tail. MK

Well . . it sorta "depends". In the instant case the FD "field" is one
of my daughters' 1/4 acre back yard, three decent-size hardwoods
spread out in maybe a 120 foot straight line and that's it. The other
op will probably be N2EY and he isn't into deep bush ops either.

I was thinking more along the lines of sniping one of the orange
barrels which are the Pennsylvania State Flower. They're quite readily
available at construction sites along the PA Turnpike and
slinky-wrapping feedline around one of those should do the job.

Let's see here, 2.5 feet diameter times Pi . . 7.85398 feet per wrap .
. yeah, that would get rid of most of the ladderline. At worst maybe
I'd need a couple of 'em in series.

QRX for the QST cover shot.

And such is the point of my illustrating the shortfalls of your lack
of experience. No one is challenging your amateur status.

The recitation of any wavelength starting with a significant three is
enough to set off alarms when there is a concurrent claim of its
visibility. That is why I said it was impossible to be a decimal
error.

Source record: 97026

```
-----BEGIN PGP SIGNED MESSAGE-----
Hash: SHA1

I have started modeling my dipole antenna with NEC2, but I've got a
question that doesn't seem to be adequately covered by the
documentation or the examples.

I have a fan dipole with various lengths of wire. The long legs are
significantly bent, and I have modeled them as two wires with
coterminous ends -- this seems to be correct. The shorter legs are
just legs. In the real antenna, the feedpoint is connected to a
length of coax such that the center of the coax is electrically
connected to the western half of the antenna and the shield of the
coax is electrically connected to the eastern half.

I can see how to set the voltage source to the western half of the
antenna, but I do not see how to set the ground to the eastern half of
the antenna without adding a ground wire. Does this really matter?

Jack.

Paul,

I just re-strung my quad last weekend. For measuring the wire, I used a wooden dowel rod, stuck through the center of the wire spool, laid across the front/rear steps of a ladder. I connected a 100' measuring tape to the same point, and then pulled away for the ladder with wire and tape held together. Worked fine. I generally add a couple of feet to each measurement, just in case the formula and my design are in dis-agreement.

Yes - the 10-10 Spring CW contest is the first weekend in May (www.ten-ten.org). Hope to work you then!

I don't have an IEEE dictionary so I stand corrected. However, 100 watts into a Yagi, Quad, Log Periodic, or 4-square and 100 watts radiated is still 0 dB gain.

Gain = 10 * Log[Pout/Pin] = 10 * log [100/100] = 10 * 0 = 0 dB.

It also has 0 dB attenuation!!!

NB: Valid over either 4*Pi or 2*Pi steradians.

>

With all due respect Bill I am not a newbie! [see below]

His beam, assuming 100% efficiency, is only 0 dB gain.

Gain [dB] = 10 * Log[Pout/Pin] = 0 dB.

The Honor Roll holder, much to his chagrin, still has a 0 dB gain antenna. He may have an amplifier that puts out 1500 watts, no feedline loss and a 100% efficient antenna. He is still radiating 1500 watts and that is by definition 0 dB gain.

The double integral of ExH across theta from 0 to Pi and Phi from 0 to Pi is constant in both cases. Therefore 0 dB gain!!!

Hi Mike:

The answer is yes and no. Some designs use the part of the feed line as a radiator some don't
The ones the don't have a 1:1 choke balun at some magic point down the feedline (if they are using coax) to stop the RF from getting into the shack, others designs use a balun at the feed point to isolate the feedline from the antenna. I think the "Carolina Windom" uses the feedline as part of the antenna and the ones that call themselves "windoms" or OFC's don't. Its all marketing and sloppy use of names.

383. Re: Homemade Antennae, help

Newsgroup: rec.radio.amateur.antenna
Date: 2004-04-08 13:31:06 UTC
From: 'Doc <w5lz@cwis.net>
Message-ID: <4075541A.32A6B7B@cwis.net>
Source record: 97034

Steve,
That 'someone' told you correctly for the most part. It
certainly
isn't the most exacting explanation for an antenna, but it will
get
you into the 'ball park'!
The length of an antenna has to be such that it provides
enough
signal to your receiver so that it (the desired signal) is
louder
than the noise. For most HF signals, 33 feet will be plenty.
Of
course, 'more' would be 'better' in some cases, but not always.
The
one thing that will do more to increase what you hear is
height. Get
the antenna as high as possible (sort of like you standing on
your
'tip toes' to see farther, right?). You also can only work with
what
you have, so if ceiling height is the most you have, then use
it.
The 'shape' of your antenna also can play an important part
in what
you hear. If the antenna is high enough above ground, it can
become
directional in nature. I wouldn't worry about that too much,
though,
just be aware of it. Stringing your antenna out as long and as
straight
as you can make it is much better than wadding it up into a ball
and
throwing it into a corner. There's also nothing that says that
you
can't change the 'shape' of the antenna, if you want to see what
would
happen.
The size of the wire used isn't going to make a lot of
difference,
as long as it is strong enough to support it's own weight. Make
it
ea$y on your elf, cot wi$e. The length isn't really that
critical
so you don't need to use a micrometer to measure the length of

your
antenna. A little more, or a little less isn't going to make a
big
difference. A foot or two is meaningless, twice the length is
"more
better", sort of.
Probably more important than anything else is how the wire is
connected
to your receiver. Use the proper connector, if possible. If it
isn't
possible, just make sure you don't short out the receiver's
antenna
terminals. Won't harm the receiver, you just won't hear much.
SWL'ing is fun, so have lots of it!
'Doc

PS - That's about as non-technical as you can make an
explanation of
a complex subject. There are 'exceptions' to everything I
said,
but what I said will certainly work for you. Knowing 'why'
it
'works' is interesting, but not really necessary to make it
'work'.
The 'having fun' is the important part...

As a G5RV is to a dipole, is your modification *really* a G5RV? Seems to me that you have a ladder line and capacitor tuned dipole, not a G5RV.

Does the 102 foot dipole have to be called a G5RV? Heck, Cecil - you might just be able to call this the W5DXP antenna. Seems different enough to me! 8^)

And perhaps your modifications actually show a little bit of why the G5RV gets a bad rap! 8^)

In the interim, I'm watching this with great interest. It might just be a great solution for me. I can get 102 feet of wire up. I have 96 feet with a tuner now.

Do You switch the capacitance in and out, or use variables? And if you switch, do you have the caps at the coax ladderline junction or in the shack?

Possible really stupid question alert!: When you speak of the ladder line being 20-36 feet, and or 25 feet for 3.8 mHz (with cap) you mean that the total height from the coax/ladder line junction to the antenna itself must be the length of the shortest piece of tuning ladder line?

IOW, If I run my coax to the roof of my house to the box I would construct to hold the different lengths of tuning line and switching electronics, I could only have the antenna roughly 25 feet above this box? If so, I can still probably get the antenna 50 feet above the ground.

Any problems with rolling the ladder line?

> I won't be suffering with a system efficiency in the mid 90's...

It would be easy to try my G5RV modification. For 3.8 MHz, it is
25 ft of "450" ladder-line with a 1000 pf cap in parallel at the
ladder-line/coax junction. I wish you would open your closed mind
and try it sometime.

> I guess this is what led me to question your choice of the perfect FD
> antenna. 80m, being the band of real issue.

A perfect FD antenna would allow one to change bands relatively
quickly without sacrificing performance. My G5RV does that.

The 110 ft dipole that I came up with has an SWR of less than 1.7:1
over the entire 75-80m band. That sure beats the bandwidth of a
resonant coax-fed dipole.

> W5DXP wrote:
>>Many hams cannot string a 130 foot dipole but can manage a 102 foot dipole.

That's not the old wives' tale. The old wives' tale is, "A G5RV
is a terrible antenna that cannot be improved to near perfection."
With minor modifications, a G5RV will compete favorably with any
other HF dipole on any HF band.

Connect the two sides of the antenna together with a wire and install
a source in the middle of that wire. Forget the coax for now. You can
expand on the model later. Something like this:

```
--------------------+--S--+----------------------
| |
-----------+ +------------
--
```

The point of the thing, which you seem intent on missing, is that EM
radiation is reflected by impedance discontinuities. Optical reflection is
very similar to what happens at lower frequencies.
I normally use this analogy when discussing the use of shielding and
absorbent materials for EMI supression.

It seems like a thousand years ago when a big discussion of glass mount antennas took place on INFO-HAMS.

(Anyone remember INFO-HAMS?)

My poor memory recalls that there was not much said in favor of glass mount antennas and a lot said against them. Most of the discussion was regarding 2-m antennas.

I think the mag mount antenna is a great invention and that's all I use for 2 and 0.7.

When traveling I put the antenna on top of the car. Around town I mount on truck lid.

> still 0 dB gain.

Dave, that's true for the entire surface of a sphere at 100% efficiency
but you are still not using the IEEE Dictionary definition of antenna
gain. From Balanis: "... the power *gain* is usually taken in the direction
of maximum radiation." i.e. not over the entire sphere but over a small
area where the radiation intensity is at a maximum. The gain over isotropic
would then be based on the ratio of maximum radiation intensity per unit area
from the beam to the average radiation intensity per the same unit area from
an isotropic antenna. To obtain the (G)ain, one can calculate the (D)irectivity
and multiply by an efficiency term.

G(theta,phi) = e(cd)[D(theta,phi)]

where anything in parentheses is a subscript. e(cd) is an efficiency
term based on conduction and dielectric losses. If efficiency equals
100%, gain equals directivity. (theta,phi) are vertical and horizontal
angles related to a chosen area on the surface of a sphere.

The cap is only on 75m to lower the 50 ohm SWR. It doesn't have to be
installed if one can tolerate a 3:1 SWR.

> Does the 102 foot dipole have to be called a G5RV? Heck, Cecil - you
> might just be able to call this the W5DXP antenna. Seems different
> enough to me! 8^)

The physical difference is negligible. It is still a 102 ft dipole fed
with a series section transformer made out of ladder-line and fed with
coax from that point to the shack.

> Do You switch the capacitance in and out, or use variables? And if
> you switch, do you have the caps at the coax ladderline junction or in
> the shack?

As I said earlier, if you can tolerate a 3:1 SWR, you don't need the cap.
Presently I switch the cap in and out by hand. My G5RV is at 40 ft. on
the ends and I just grab the feedline and pull it down to access the
ladder-line/coax junction where the cap is installed for 75m - thus
eliminating the need for a tuner. It only takes a minute or two to pull
on the feedline and plug or unplug the cap. I hope that's clear. Here's
a diagram for 75m operation:

XMTR---any length 50 ohm coax---+cap+---25 ft. 450 ohm feedline---102' dipole

The parallel 1000 pf cap is across the two feedlines at the twinlead/coax
junction.

> Possible really stupid question alert!: When you speak of the ladder
> line being 20-36 feet, and or 25 feet for 3.8 mHz (with cap) you mean
> that the total height from the coax/ladder line junction to the antenna
> itself must be the length of the shortest piece of tuning ladder line?

Maybe a confusing question? I have 8, 4, 2, 1 ft pieces of ladder-line
that I insert between the 21 ft. minimum length of ladder-line and the coax.
That allows me to vary the length of the series section transformer from 21
ft minimum to 36 feet maximum. Obviously, I could use one more length to
increase it by X amount.

> IOW, If I run my coax to the roof of my house to the box I would
> construct to hold the different lengths of tuning line and switching
> electronics, I could only have the antenna roughly 25 feet above this

> box? If so, I can still probably get the antenna 50 feet above the ground.

I had envisioned mounting the box on a 2x4 sticking straight up at the middle of the dipole. But I could probably mount the box on my roof.

> Any problems with rolling the ladder line?

DON'T ROLL THE LADDER-LINE! Keep adjacent loops at least six inches apart. Here's an idea that I have been toying with. It involves varying the length of the coax as well as the length of the ladder-line to maintain a constant total length of feedline. This is a physical solution to the mechanical problem and has virtually no electrical effect.

```
XMTR-----coax------------ ----coax---- ------coax------
A B C
==twinlead== ====twinlead==== ==twinlead==dipole
```

This is for illustration only. Not all the switchable lengths of twinlead are shown. Only two are shown.

We need a DPDT relay at A and C. We need a 4PST relay at B and other points like B. For minimum twinlead, we could have a coax to coax connection at points A and B and a coax to twinlead connection at point C. For maximum twinlead, we would have a coax to twinlead connection at A and a twinlead to twinlead connection at points B and C. The physically parallel coax and twin lead would have to be physically separated, maybe one on each side of a 2x4 about a foot apart.

An SWR sensing circuit could be added to turn this thing into an autotuner for a G5RV. Hope I didn't get carried away. These are just some random thoughts toward perfection of the G5RV.

394. Re: aerial coupling and nec2 - I do not understand my results

Newsgroup: rec.radio.amateur.antenna
Date: 2004-04-08 16:46:30 UTC
From: stuart macgregor <stuart.191@ntlworld.com>
Message-ID: <pan.2004.04.08.16.46.30.368735@ntlworld.com>
Source record: 97045

The replies so far do not seem to address the issue I was trying to get help on.

I expected a linear, signal independant symmetrical toeplitz mixing matrix, due to aerial coupling in the symmetric layout.

As far as I can see this would be (I-K)^-1 where K(i,j)=K(j,i)=k(i-j)=z(i,j)/(z(i,i)+zload) and K(i,i) is defined as 0. I may be wrong, this was just from first principles.

What I got from the nec2 calculations was a linear symmetrical toeplitz mixing matrix which *varied* with signal direction. I am probably missing something obvious?

As to looking at the RP - I wanted to have a look at the RDF calibration problem, and I do not see how to exploit the radiation pattern for this.

The aerial pattern I tried finally was just 3 similar thin resonant dipoles with 0.8 wavelength spacing on a circle. No joy so far.

395. EzNec Demo simple Example sen me please! :-((

. . . .

Cecil check me here if you will. I brought up a CAD program to sketch your 80/75 dipole and ran into a puzzler as soon as I started to draw it. Center fed 110' flattop, 110' balanced feedline. No problem. The question arose when I tried to lay in the tuning caps. My understanding is that the "input" sides of the two caps are connected to each of the two wires at the "output" end of the feedline. Then the "output" side of one cap goes to the shield of the coax and the output side of the other cap goes to the center conductor of the coax. This is not possible with a typical double-section variable BC-type cap because one side of such caps is a common ("ground"). A pair of caps mechanically coupled via an insulated shaft coupling but completely isolated electrically from each other should work. Where's the glitch??

Hi Dave,

I certainly am missing something from this post. How do you get from
my comment about visible wavelengths to one about shielding EMI?

All depends on the situation. Last thing ya need on FD is more
complications.
Which is why I've gone with coax-fed dipoles on FD for years.
>
The books give all sorts of figures for "open wire line". But many of
them are for the classic lines made of #14 copper spaced 4 to 6 inches
with ceramic spreaders every few feet. Brown poly TV twin lead with
rectangular holes punched in it is a whole 'nother ball game.
'Specially at high SWRs and when it's wet. Which may not be a
consideration in NTX but is a big consideration in EPA.

Until the rain falls or the wind blows or somebody walks into it in
the dark.

Biggest headache, though, is switching the various lengths for
different bands.

> . yeah, that would get rid of most of the ladderline. At worst maybe
> I'd need a couple of 'em in series.
>
> QRX for the QST cover shot.
>
If it were me, (which it ain't) I'd either go with a coax fed parallel
or trapper.

Or build a nice split-coil balanced tuner and run the ladder line
right to the tuner. Real ladder line, or at worst that "fretline"
stuff (which I have squirreled away). Lessee, I got the splitstator
cap, and some nice coil forms, and a smaller cap for the link. Oh
yeah, some real all-copper alligator clips for the taps....

Or do it AG6K style.

--

The big question for any FD antenna is "how many QSOs"? All the
simulations and Smith charts don't count for any points - QSOs do. My
personal best is 629 QSOs with one 100W rig, one op, one mode, three
bands and two antennas. Coax fed trapper set up as inverted V for
80/40, quarter wave groundplane elevated 5 feet with 8 sloping radials
for 20.

Anybody here beat that on FD with only dipoles and verticals?

> mechanically coupled via an insulated shaft coupling but completely
> isolated electrically from each other should work.

Yes, that's what I had in mind. Mine are side-by-side with a
non-conducting fiber-chain connecting the shafts. Same with my
two rotary coils. When I said "dual-ganged", I meant mechanically
ganged, not electrically ganged.

```
| |/
Coax center wire--------|/|--------feedline--------
/| |
ganged variable caps to dipole
| |/
Coax braid--------------|/|--------feedline--------
/| |
```

And of course, there needs to be a choke between the coax and
the caps.

<Cecil.A.Moore@ieee.org> wrote:

>Take a look at the frequency chart in the "Reference Data for Radio
>Engineers" and you will see why someone with poor eyesight might
>make that mistake.

I duly note at the top of the graphic the expanded "Visible Spectrum
in Microns (Micrometers)" which clearly offers 4 cardinal points none
of which has a leading three (3) as a wavelength specification. Now
"clear" may be an unfortunate choice of wording, but the separation of
topic which is part and parcel to the issue of glare with its
corresponding distinct and uncluttered typeface offers far less
ambiguity. [Others may wish to observe the 610nm specification
offered as "red" in other correspondence is distinctly yellow here.
Such is the plight of subjectivity and the illusion of human
perception.]

As glare is another illusion of human perception of visible light it
follows that there is no specification of it, nor visibility for any
wavelength starting with a 3. It matters little how many decimal
points you slipped on the occasion of visiting the extreme lower edge
of the infrared. If you had misquoted 6.35 MILLION Angstroms instead
of 6350 Angstroms that would have passed with little comment.

All of this is commonplace to a practitioner of the art of Optics and
OptoElectronics.

This, then, returns us to the topic of through-glass attachments,
their loss, and the contribution of the layers to reflect (a la glare
suppression) which you re-introduced to this thread, above. [I will
suspend the absurdity of this logic for the moment.]

What is the resonant frequency of this adhesive layer:
in wavelengths, frequency, or color? I think we can all agree
(barring the slipped decimal place) that it is not 2M nor 440 MHz.

I will go one step beyond and ask, if this geometry of attachment is
variable through curvatures (windshield are always curved) what are
the prospects of Newton's Rings offering a variation in that
determination?

These are all garden variety questions that plague newbies to the art.

No switching the various lengths on this one, Jim. Just a 110 ft dipole fed with about 110 ft of fixed length ladder-line with two series variable caps as the one knob tuner. Covers from 3.5 MHz to 4.0 MHz with an SWR less than 1.7:1 and no lossy coils needed.

All simply an argument for engineering through democratic vote. I
wouldn't cross a bridge designed that way.

I have a 100W transmitter, name me one antenna that will radiate more
than 100W from this source. Then we can put a "gain" figure to it.

Thanks guys.

All of these ideas make sense. It appears that I am just too *close* to this station to get decent nighttime reception --- just the opposite of the normal situation. There seems to be a relatively small band of distances within the xmitter's night pattern where the ground and sky signals alternately cancel and re-enforce each other on a random basis after local sunset.

Thanks,

Dave Pitzer

Anyone know of a listing of Broadcast Band stations by frequency? (i.e. all stations on, say, 770 KHz.)

www.radio-locator.com lists by location (city), format, or call-sign, but not by frequency.

I'd like to know all stations broadcasting on, say, 810 KHz.

Thanks,

Dave Pitzer

Hi Steve,

Looks like a really nice rig. One comment to add to Doc's advice: add
a tuner between your antenna and the rig. The reason is that nearby
AM stations can overload and saturate your front end without you
knowing it and reduce the sensitivity considerably! This is not so
obvious with a whip antenna, but it becomes a big time problem with
longwire antennas if the front end is not tuned (a very expensive
feature, unless you go back several generations to tube models).

You can buy a cheap one that is already used by an amateur (or go for
the absolute cheapest model without meters that would do you no good
anyway). Or to cut cost even more, build your own (browse the net for
designs).

Hi Dave,

Try a loop antenna turned/layed-over to reject the interfering
sky/direct signal. Perhaps not a sure bet, but maybe 50-50.

I apologize to everyone for a mental blunder I made with this
proposed antenna. The reactances are capacitive, not inductive.
It would have to be tuned with series inductors which defeats
the propose of a low loss design.

The ONLY difference between antenna directivity and antenna gain, by
definition, is efficiency. Therefore, it logically follows that you
are asserting that no antenna possesses directivity. Care to prove
that outrageous assertion? Maybe you better stick to optics?

What you've calculated here is efficiency, not gain. It's important to understand the difference between the two if you want to communicate with others about antennas.

How much reflection is there from a device with sub wavelength
dimension? Cecil can't answer this, can you?

Let's cast this back to optics:
You have a mirror with 60nm sides
(a similar, proportional scale to the glass mount).

The question becomes, how much light (percentage or dB) is reflected?

For others following this: would you use this mirror to shave? ;-)

422. Horizintal loop with two feed points?

Newsgroup: rec.radio.amateur.antenna
Date: 2004-04-08 20:04:12 UTC
From: "T.E.O" <rfmscpa@earthlink.net>
Message-ID: <0fidc.2002$A_4.227@newsread1.news.pas.earthlink.net>
Source record: 96973

Many of us use 1 wl horizontal loops configured in a square or rectangular shape. When these loops are operated at frequencies greater than the fundamental, the horizontal pattern changes from a nearly circular pattern to one with lobes & nulls.

For example, if I operate a 60' high, 1 wl, side fed, square, 80 meter horizontal loop on 40 meters, the horizontal pattern is that of a 4 leaf clover with four fairly broad lobes and four nulls.

Now this is great if you intend to QSO with a station in the direction of a lobe but not so great if your target is in the direction of a null.

Now if I move the feed point to an adjacent side of the square, the lobes become nulls & the nulls become lobes. In essence, I have "rotated" the pattern by
moving the feed point.

I have attempted to take advantage of this shift in pattern by erecting a 160 meter loop that "floats" in pulleys at the corners. I then tried to physically drag the loop wire through their supporting pulleys & move the entire antenna wire until the feed point was where I wanted it. This was a really stupid idea & did not work out due to the weight of the
wire, binding at the pulleys, mechanical problems, the hassel of "rotation" , etc., etc. & I have
abandoned this idea.

I'm thinking now that I should just add a second feed line on a side adjacent to the original fed side and simply select the feed line (and pattern) that suits my operating needs. Like this:

```
********************************** *
* *
* *
* *
* *
* *
* *
* *
X *
Feed (1) *
X *
* *
* *
* *
```

* *
* *
**********XFX**********
e
e
d
(2)

My problem is that I'm not sure of the effect of adding that second feed line. Should the unused feed line be grounded or simply left unconnected at the transmitter? Or should I use relays at the feedpoints to "jumper" the unused feedline? I use 450 ohm "window" type ladder line.

Or, as another ham has suggested, put up a second loop, spaced a few feet down from the first loop, & feed it where I like.

My goal is an antenna that covers 160- 17 meters, & has some capability to steer the "gain" on the
frequencies greater than 2.0 mc.

Any help/comments will be appreciated.

Source record: 96977

I've successfully used two feedlines for a single antenna (my "Field Day Special", for reversing the direction) by making the feedlines an electrical wavelength long and leaving the unused one open. In my case, I wanted an open at the unused feedpoint, rather than a short as you do. Also, you don't need that much length. Either of these should work for your antenna, producing a short circuit at the connection point of the unused feedline:

1. Make the feedlines an electrical quarter wavelength long and leave the unused one open circuited.
2. Make the feedlines an electrical half wavelength long and short circuit the unused one.

Whichever one you choose, don't "ground" the unused feedline or connect it to anything else.

Anyone else trying this method should be aware that even a small amount of feedline loss translates into a poor open or short at the antenna, so loss usually has to be considered. In this particular case it won't be a problem.

At LF and MF there is a distance from the transmitter at which the ground wave and sky wave have roughly equal strengths. Distance varies throughout darkness.

As the height of the reflecting layer varies the path length of the sky wave varies and so the relative phases of the ground and sky wave changes with time between being in-phase and out of phase with each other.

The relative phases of carrier and sidebands are affected differently because of their different wavelengths. Carrier phase shift causes variation in signal strength. Sideband phase shift causes severe audio distortion.

EZNEC comes with some of the best documentaion around. I suggest you print it out and do a little reading. Following that, do the "Test Drive" section. When you finish that you should have no problem modeling the antenna you describe.

433. Statement on Spam and VoteNader.org

Newsgroup: rec.radio.amateur.antenna
Date: 2004-04-08 21:06:04 UTC
From: donovan@votenader.org
Message-ID: <ce5e6baf.b5ed5ba5@host-69-48-73-244.roc.choiceone.net>
Source record: 96995
Cross-posted to: rec.radio.amateur.antenna,rec.food.recipes,rec.arts.marching.misc,rec.music.gaffa

Spam from VoteNader.org? (Or naderexplore04.org)

You may have received spam email recently that appears to come from our campaign, or be about our campaign -- perhaps the "From" and or "Reply-to" addresses look like they are coming from VoteNader.org. Or perhaps you have received a message that appears to come from an individual (if the address is real, the real owner probably did not send this email either) with suppressed recipients. Or maybe you received an email that appeared to come from yourself promoting our site.

These messages are NOT from Nader for President 2004, and these email tactics are NOT condoned by our campaign in any way.

UPDATE: Some of the latest forged emails have been made to appear to be coming from naderexplore04.org. Again, we are not responsible for this unfortunate abuse of email, and there is little in the technical sense that we can do to prevent this as it has nothing to do with our actual infrastructure. We are collecting information.

NOTE: The emails with malicious code (viruses, worms, etc.) often have attachments. Our campaign will NEVER send attachments in our announcement emails to you. Please be sure that you have anti-virus software and have the latest updates available for your anti-virus software.

Our hosting service has alerted us to say that Nader for President 2004 appears to be the target of what is called a "Joe Job." Such an event is where a spammer forges email to make it appear to have come from some other domain (such as ours -- or yourself). This is hard to prevent on our end and part of the insecure nature of the email protocol in general.

Members of our actual email list must request to receive email from us (either through Ralph's signup sheets or subscribing during our exploratory phase, or now on our campaign site). When one signs up for email they must reply to a confirmation message before they receive our list announcements.

Our public announcement emails come from "campaign@votenader.org," contain a "Paid for by Nader for President 2004" statement at the bottom, and have "updates@lists.votenader.org" in the "To:" header. Unfortunately, some of these indicators can be forged as well.

Most of the Spam that we have received complaints about appear to be forged from email addresses not associated with votenader.org (often forged to appear to be coming from government email addresses), and have

our website code embedded in the body of the email with hidden tags that contain random words that work to subvert anti-spam software.

If you are on our lists, you can ALWAYS unsubscribe at ANY time by following the instructions included at the end of our announcements. You can also use our unsubscribe page using the email address you signed up with.

If you are receiving this SPAM, we extend our apologies.

We will pursue the spammers to the full extent of the law.

For more information, please review these resources:

How Do I Determine the Source of an Email?

The operating frequency. It should work adequately over a single band, but not multiple bands. At frequencies near, but not exactly at, the frequency you've cut the feedlines for, the effect will be that a little reactance will appear at the point where the unused feedline connects. This will make the antenna tune a little differently, but have no other significant effect. Far away from that frequency, though, as on another band, you can have some wild impedances at the second feedline connection point, resulting in a very different pattern and impedance at the active feedpoint.

Has anybody given any thought to what an antenna tuner of any kind
adds to your enjoyment in ham life. I have the MFJ 3kw tuner
with the roller inductor and differential capacitor and what a
charmer it is. I dont worry about my inverted dipoles mostly
Vertical polarized. I just crank up on any freqcy between
1.6 and 30 mhz and dont give a dam about gain or lack of same.
It just makes life so ez to do it that way. Why you ask.
Because it protects the ic751's output stages. Think of the
tuner as a RF SUCKER, it just sucks all the dangerous stuff
out of the rig and puts it in the tuner. How much of that
power gets finally radiated I could care less. I work
mostly on MARS freqcys and none of them are inside the ham bands
so this tuner serves me well.

==========

The loss at 30 MHz with a very high SWR is on MY chart.

And the loss in properly used coils is very small.

But either way, the difference between the two methods is so small you are unfairly claiming an advantage in the use of transmission lines. Do some accurate calculations to see what actually happens.

Reg.

Cecil, Looks to me like a 108' flattop, 40' up, fed with 44' of 450 ohm line might get less than 2:1 across 80 meters with 250pf variable caps. The magic numbers are 3.8 mhz and 132pf for 1:1. No lossy coils.
I have some silver plated roller inductors that I use in a re-configurable "L" network that I'll bet used with the above antenna will produce efficiencies near what the vari-caps will, and 1:1 across 80M. I really don't think the silver plating has that much to do with it.:-) Anyway that is what I have used on Field Day.

Exactly how can coils replace the transmission line it takes to get
the signal from the hamshack to the antenna? I would love to eliminate
my transmission line but I don't know how.

Thanks Gary, with a little modeling and experimentation, almost any
reasonable antenna problem can be solved. It's not enough to say,
"A G5RV is a terrible antenna". The question that should be asked is,
"Exactly what is wrong with a G5RV and how can it be fixed?"

Although your method works well you unfairly attribute it to the G5RV. This undeservedly attaches prestige to that over-rated antenna.

Immediately you change the length of the feedline from 1/2-wavelength at 14.15 MHz it is no longer a G5RV.

And in addition to a top length of 102 feet there is an enormous number of other top lengths which will work in the manner you describe. 102 feet is no more magical than 118.5 radials.

Do you hold shares in a G5RV manufacturer? ;o)

3/4 wave on a ground plane has a main lobe about 50 degrees above the horizon. I have a paper by Inagaki et. al. from the 70's describing a 3/4 wave on a gnd plane if I recall, 1.6 lambda or was it 0.6 from a 60 degree corner reflector. Built one for 2304 MHZ It gives 18dB gain (probably dBi) and has a very good 50 ohm match. My dad built one in a 2 foot cube for a 440 antenna gain contest {it was a bit short compared to the paper's specifications) and won.

There was a feller in north Denver a couple hundert years ago that
had a rotatable rhombic. He had a circular track in place for ore
carts -- he had four ore carts with telephones poles installed in
them (with concrete, or the somesuch.) This was *LONG* before
(affordable) digital electronics and I am unsure how he co-ordinated
and synchronised travel of all 4 ore carts.
I know for sure that he had a lot of acreage, _and_ a very
understanding wife...

A G5RV is a terrible antenna if it did not do well the last time you used it. HF antennas and propagation being what they are, it is difficult to label any antenna as terrible.
A G5RV type antenna in its many configurations ought to work as advertised.
And as you have proved Cecil, it can be tweaked.

OK , I got off on the wrong foot, this is more better. Tnx for the
clarification. Now back to Autocad so that I can enshrine it for
posterity . .

There are a lot of nice inexpensive instrument-quality parts out there
which make it quite easy to mechanically couple variable caps, rotary
inductors and I guess even pots but I've never seen that done. I'm
partial to the miniature timing belts and gears. IF they're not
wire-reinforced belts. For this tuner job there are plenty of options
available.

I had a monster remotely controlled tuner in the back yard for years
for my end-fed 135 inverted L. I used a pair of old WW2 Navy gun
director synchros, one in the shack which I cranked with a turns
counter and the other in the tuner cabinet to spin the big rotary
inductor via a small timing belt, never missed a lick.

From: Steve Nosko <suteuve.nosukowicuz@moutouroula.com>
Message-ID: <c54nla$qi3$1@newshost.mot.com>
Source record: 97007

I finally got around to scrubbing the manual for my 269 (was sick for a few days) and played with it and made a quick reference sheet showing the menus and what is displayed in each one and which buttons to push... The distance to fault process is confuling to get from their description, but easy from a flow chart.

Anyway... Is the following a known problem?

In the Advanced 3 menu for NON-50 ohm system measurements... With a known good 75 ohm load when set to 75 ohms mine shows a 1.3 : 1 SWR. The load shows as 75 ohms when using either the "normal" 50 ohm main menu function or in the Advanced 3 menu (when set for 75 ohms). It actually reads something like 75 & J10 in the Zo menu - which is still very near 75 ohm magnitude.

The first call to their tech assistance line yielded a guy who clearly didn't understand and tried to tell me it only measures in a 50 ohm system - EVER. He couldn't explain what the Zo setting was for in the Advanced 3 menu--at least not coherently. I called the next day after carefully reading the manual to assure myself that my understanding was correct. After a little uncertanty this guy said to send it in for calibration.

1- Does this make sense? Isn't this simply a computation to do the '50 to whatever ohm' translation? They CAN'T be changing anything on the bridge.

Has anyone used this function and did yours read correctly? I know not to expect lab performance, but this ain't even close.

Exactly. So ya get a bit more loss when it rains on a G5RV, who cares?? Lemmee cite a good recent example of why too many people fuss too much with dB. here dB. there details.

I was watching ops at the N3RS multiop station during the ARRL CW DX contest in March. Late in the contest the guy in the 20M seat was knocking out contacts as a respectable rate. The xcvr was an FT-1000 and the amp was a big remote-controlled ACOM. After some considerable amount of time he finally noticed that the amp had faulted and swithed itself offline when he changed bands to get on 20M. He'd been running barefoot the whole time without realizing it. The problem was sorted out, the amp was reset and off he went again this time with full power. His rate did not change by any discernable amount even though his "losses" went down by what . . 12 dB?

So no, I am not gonna get my knickers in a twist over the collection of incidental losses one runs into with FD antennas and tuners. As you imply there are far more telling factors which determine the effectiveness of any station.

OK, change of topic here, I'm game. Anybody out there have well over a hundred countries confirmed on both 80 and 40 by using just a single length of end-fed wire for the antenna?

I don't have much use for one, even if I wanted to. I'll never dump my
dipoles to change to a G5RV. I'll never use an antenna system with a
coax/choke/ladder line feed either. Sorry...But feel free, if you want
to...

The only bands I work at FD are 80 and 40 CW. I use parallel dipoles
at right angles. My band change is instant. If for some reason I get a
wild hair, and decide to try 20, I get on the beam. I never go any
higher than that, because it's always night when I operate. I don't do
anything in the daytime except set up my junk, and then lounge around
and look useless for a while....:/ I then go home, and come back later
in the night and operate when it's cooler.
>
> The 110 ft dipole that I came up with has an SWR of less than 1.7:1

Who cares if I don't move more than 100kc all night? I zig zag back
and forth from 3500 to about 3600...7000 to about 7075 on 40..
>

> other HF dipole on any HF band.

I guess your idea of "near perfection" is different than mine...I agree it can be improved quite a bit, but I'll reserve comment on the "near perfection" part...
If I wanted a multi band dipole using only one element, I would use a 80m dipole, with insulators at each point, for each band. I then use jumpers to bypass whichever insulators I want for a certain band. I prefer that method to yours because the feed stays at 50 ohms appx, and the pattern is a normal dipole pattern on any band I use. To me, this is more "perfect" than your method, as it retains my preferred "50=50=50" policy. :)
But it's all personal preference...Below would be a 80/40/20 version, which also works 15m on the 40 leg. I've used this method many times.

o----------------o----------o----------00----------o----------o---------------o

But for what he originally wanted as far as covering two parts of 80m, with one antenna, I still would prefer paralleled dipoles, cut for each section of the band. I would run them at right angles like a turnstile. The SWR curve will look like a "W". Solves his problem, and is still ultra efficient with no caps to diddle, weird feedline combos' etc..Add 40m legs, also in parallel, and it's instant bandchange between both parts of 80, and also 40. Won't have to do a thing except dial the radio around...I think he said he's already got the high bands covered...To me, thats the "perfect" antenna for his problem, and what I would run in his case. But to each his own I guess... MK

Sure, I could drop a line down to ground, but the antenna itself
doesn't work that way. It goes down a long coaxial line to the
transmitter, at which point the shield is grounded and the center
conductor is connected to the signal. Does that matter?

This stuff is black magic, I tell you.

Jack.

ASCII art fails me, Jack. You can model the coax
as a wire to ground, but that wire has to have all
the geometric twists and turns that your actual
coax takes getting to the transmitter. The coax
shield is part of your antenna system; it radiates
along with both sides of the dipole. And even at
your transmitter, "ground" isn't really ground.
There is a connecting wire between the transmitter
case and "earth" ground.

In reality, there is no such thing as "ground" with
RF.

The reason your post caught my eye is that I have
the same antenna system you do - coax-fed dipole
with no balun - and had to model my coax line
shield to get "real" EZNEC results.

Lets not throw the baby out with the washwater, this ain't over Cecil. In fact it opens up possibilities. Fact is that very few ops who get on 80/75 use anywhere near the entire 3.5-4.0 segement, it's a function of one's specific interests and reasons for using the band. In my own case I'm a basically a DXer thus my only real interest is in just the 3.50-3.55 and 3.70-3.85 Mhz slices of the band. And in being able to have a single, simple antenna which presents low feedpoint SWRs in those frequency ranges. Which rules out conventional dipoles and most of the rest of it's relatives.

In the case of your 110 foot flattop with it's 110 foot feedline and for my specific purposes the "tuner" would be a pair of inline lo-loss fixed coils with taps which are selectable with a simple two pole two-position ceramic rotary switch. Or make it a three pole switch and be able to ground the antenna. Three taps yields three slices, etc. A tuner like that would be a whole bunch easier to build and use and would require much less mechanical claptrap than the original pair of variable caps scheme requires.

However if using your 110 foot run of ladderline and coils configuration is a hassle but a 44 foot feedline would work Mr. Boyle's design can be used to get the same basic performance results with the caps. The thread has produdced a couple good approaches for practical solutions for an old problem and they both go into my keepers book.

Hi Fred,

You should be able to measure continuity from the connector pin
(center conductor) out to the antenna radiator (the whip). Measuring
continuity for the shield is not always guaranteed for a mag-mount.

Reg Edwards wrote:

> Richard Clark,
>
> I fully support your "All antennas have zero gain" campaign.

IMO applying the word 'Gain' to an antenna is misuse of the word 'gain'.

Beam forming antennas do concentrate the RF energy into an angle less than 2*Pi steradians [Hemisphere] but the total energy concentrated is still the power applied to the antenna minus losses. The far field from a beam forming antenna is more intense than from an isotropic antenna.

Maybe the better term is to quote the solid angle at the 1/2 power points in the E and H plane as a figure of merit. Example: antenna A has a 1/2 power beam width of 2500 square degrees while antenna B has a 1/2 power beam width of 1800 square degrees.

Ah! But there are techniques for measuring TRUE VSWR!! [Not my little Daiwa 101C or even the trusty Bird.]

Nope, I used to measure TRUE VSWR [in 1958] using a General Radio Slotted Line with moveable probe!! I've forgotten the plotting details but the answer came from plotting the response over 1/4 wavelength on a SMITH Chart. Ain't cheap but it was accurate.

Seriously, I wonder if any readers recall the details of measuring and plotting based on the GR Slotted Line?

Next question: where do I get a 160 meter 1/2 wavelength 50 ohm slotted line?

It's essentially moving the loading coils from the antenna to the
hamshack and, according to EZNEC, gives a 1.1:1 SWR from 3.6 to
4.0 MHz. SWR goes up to 1.5:1 on 3.5 MHz.

It will be interesting to apply Mr. Boyle's design to your particular
two-segment problem.

480. Earth loop somewhere- humming sound

Newsgroup: rec.radio.amateur.antenna
Date: 2004-04-09 15:56:02 UTC
From: Gerhard Beulke <palmcove@email.com>
Message-ID: <MPG.1ae1648d323358979897ac@News.individual.DE>
Source record: 96930

Hi,

I couldn't find any better Newsgroup to ask this question.
It's about a TV antenna.
When I try to capture a video from a VCR (the VCR is connected to the antenna), I get a humming audio signal.
When I unplug the aerial cable, it's gone.
The antenna is installed on the roof and is proper earthed. In between is a booster. I don't know if the booster causes the trouble but it shouldn't.

The humming sound is only there when the VCR is connected to the PC (via firewire) and the aerial cable is plugged into the VCR.

Any tips how to solve the problem would be greatly appreciated.

Hi Gerhard,

One way that is quick, but not always effective, is to put a "ground
breaker" between your equipment's power supply and the mains. I'm not
sure if this is available for European AC connectors.

Another way is to use extension cords so all equipment that is powered
connects to the same mains outlet.

You say the antenna is "properly grounded." This is suspicious. Does
it have a wire going to the SAME ground (earth) connection as the
mains? If not, then connect the two together. If the first two don't
work (and even if they do), your problem is probably from this "proper
ground." The reason for the name "ground loop" is that you have two
different paths to ground (two different ground connections separated
by earth).

C'mon Bill,

Redefine antenna gain? Where? I simply removed the option of calling
it absolute gain that is more in the province of active amplifiers not
passive lenses. The thread is already 28 posts too long - it isn't
rocket surgery.

Mark as usual one size does not fit all. Particularly when antennas in
small back yards with limited antenna support options come into play.
Which is what I'm dealing with. If I had enough real estate available
to put up crossed coax-fed dipoles/vees I'd probably do that. But as I
pointed out earlier I don't have enough real estate, not even close.
So your solution is irrelevant here.

The jumper-to-bandswitch antenna would work IF one was (a) able to
drop and hoist the antenna quickly and conveniently (b) was inclined
to futz around in the dark to change bands. Which I'm not. I've
installed dipoles at this site before, the trees I use for supports
are gnarly beasts, simply dragging one insulator per end per weekend
thru the things is a major hassle. There are still a couple end
inulators dangling in 'em from previous (broken) antennas so that
elimimintes the quick up/down idea and hauling multiple insulators
and/or traps thru 'em.

I *might* have 20 & 15 covered *if* that antenna works. But I don't
know yet one way or the other so I'm still planning on an
off-the-shelf G5RV to cover my butt this time around unless a better
idea come up. I've used G5RVs before, they're far from my favorite
type antenna mostly because of the need for a wide-range ATU but they
do work and are applicable to a much wider range of installation
conditions and restrictions than any other type of coax-fed multiband
HF antenna that I know about.

Dave Shrader <david.shrader@comcast.net> wrote:

>IMO applying the word 'Gain' to an antenna is misuse of the word 'gain'.

Since this particular terminology has been used in this way in both amateur and professional antenna literature for more decades than I've been alive (I'm pushing 50) I think you're tilting at windmills to try to eliminate it, or to declare it "misuse".

I personally prefer to refer to what an antenna delivers as "directional gain", to distinguish it from the sort of "more RF out than RF in" power gain that an amplifier delivers. From the point of view of someone trying to deliver a specified amount of power to a receiver in a specified direction, the two types of "gain" can be interchanged to a large degree.

Yes, they're distinct, and we need to remember the distinctions, but they can be traded-off against one another in many common sorts of calculations.

[At the risk of re-opening a topic of contention, I'll posit that the use of the term "gain" to refer to both amplifier power gain and to antenna directional gain is somewhat similar in spirit to the use of the term "resistance" to refer to both dissipative and nondissipative impedances. Each is a single term, referring to two different phenomena which can under many circumstances behave in ways which can look equivalent from a particular point of view.]

>Next question: where do I get a 160 meter 1/2 wavelength 50 ohm slotted
>line?

Go down to your nearest abandoned rust-belt factory that has a large brick or concrete chimney, wrap the chimney with sheet tin (leaving a slot), and drop a suitable-sized silver-plated cast-iron sewer pipe down the center. Run your probe up and down the chimney on a huge pulley.

It'll probably be tricky to couple this to the antenna and feedline, though. I don't think even Andrews makes a heliax connector quite this large.

That'll be a royal pain in the butt, to put it kindly.

Jim> The coax shield is part of your antenna system; it radiates along
Jim> with both sides of the dipole. And even at your transmitter,
Jim> "ground" isn't really ground. There is a connecting wire between
Jim> the transmitter case and "earth" ground.

Actually, at my station. the water-pipe ground is connected to the
antenna tuner's ground which is connected to the transceiver's ground,
but I get your point.

Jim> In reality, there is no such thing as "ground" with RF.

This appears to be one of those subtleties that has slipped past me.

Jim> The reason your post caught my eye is that I have the same
Jim> antenna system you do - coax-fed dipole with no balun - and had
Jim> to model my coax line shield to get "real" EZNEC results.

Interesting. I do actually have two current-mode baluns -- the
feedpoint has eight or nine turns of coax that were wrapped around a
coffee can before being tied down and the coffee can removed, and the
transceiver has three turns of coax through three large rare earth
magnets. How does one model those with NEC2?

488. 6m vert dipole

Newsgroup: rec.radio.amateur.antenna
Date: 2004-04-09 19:13:07 UTC
From: Tyas_MT <tyas_mt@hotplonkmail.com>
Message-ID: <4076f5cd$1@news.vallnet.com>
Source record: 96939

I'm planning on making a 6m vertical dipole, using a tube lower element (shield side) to run the coax to the center point.
I have an almost perfectly sized stainless steel whip (old CB antenna), and already have a slightly longer section of copper pipe to use for the bottom that I can easily cut down. A friend that makes custom plastic stuff says if he has the proper sized scrap he'll bore and cut a plastic insulator/whip support for me... if not he'll get the stuff at cost.

Mounted sideways it would look something like this:
- Steel Whip
+ Feedpoint/section insulator/whip support
= Copper pipe with feedline (coax) running through it to feed point
------------------------+===============
Left side connected to center conductor at feedpoint
Right side connected to shield at feedpoint

What I'd like to know is if it is going to have a major effect on my dimensions/bandwidth/anything else if I use different materials for the two sections of the dipole (steel for the whip, copper for the pipe)? And what kind of effect is having the two different element sizes going to have as well? (I know increasing element sizes tends to raise overall bandwidth, but not sure how only one element will effect the antenna as a whole.)

Also is there going to be any effect from the capacitance between the shield braid of my coax and the antenna segment surrounding it? The website I read this from didn't mention that, though they did say you may want to coil the feedline about 4-6 turns about another quarter wavelength from the end of the antenna.

Thanks in advance
73

Hold on Bill!! I posit a 6 element long john yagi in free space with 1500 watts at the feedpoint.

If I assume 100% efficiency, no losses in the antenna and antenna materials, and then calculate the power in the surface of the resulting pattern do I not get 1500 watts?? That's 0 dB gain!!!

This is common language and correct Physics.

THE ANTENNA HAS NO GAIN !!!!!!!

Now, for the sake of accuracy the antenna PATTERN will have a different pattern from a dipole or an isotropic antenna. The antenna pattern yields a field intensity that is greater than the reference antenna's pattern.

So, the correct gain terminology must speak in terms of resulting PATTERN not the antenna.

'Antenna gain' is both loose and incorrect language notwithstanding advertising and marketing claims. 'Antenna Pattern Gain' or 'Directional Gain' is correct language.

On my 40M inverted Vee, I put 4-5 turns in teh coax and a couple of
clamp on "beads" several years ago and haven't had any problems. I had just
gotten got back on the air and remember seeing both the "coil-up-your-coax"
and "bead-type" baluns, but didn't remember the specifics, so I took a shot
at it with what I call the K9DCI choke-choke balun. hi hi

What's 'GR' ? Never heard of it.

Never-to-be-forgotten, I first measured SWR on a laboratory bench slotted line in the town of Stockport near Manchester around February 1944. V1's and V2's, Hitler's secret weapons, were falling on London and S.E. England. The 1000-bomber raids by the RAF on German towns and cities, the fire storms directed by Air Marshal Bomber Harris, were building up with an ever increasing ferocious intensity. One night 110 heavy bombers failed to return to base. The death toll in Europe and Russia had already passed the 15 million mark.

I remember it was raining at the time. It always rains in Manchester.

There were two simple relative voltage measurements spaced 1/4-wavelengths apart. Values of Zo, Zg, Zt and Gamma were quite irrelevant. The only mathematical equation was SWR = V1/V2. And that's all there was to it!

So began my radio education.

Reg, G4FGQ

It seems to me that there are two major issues with the Lattin/W4JRW
antenna:

1) Mechanically, it can be challenging. Regular Twin Lead with one of
the wires cut is just too flimsy. If you use spreaders and such it's
not simple any more. What's really needed is for somebody to make
"tubular" Twin Lead with, say #16 or even #14 copperweld conductors.

2) The velocity factor of the Twin Lead is a challenge to model
because the stub sections radiate on some frequencies but not others.

The thing is really just another form of trap antenna.

I get the feeling that Lattin either went through serious math pushups
to get his design, or cut up a lot of Twin Lead, or both.

I can (a) release the pulley on either end of my antenna or just pull
on the feedline to get at the jumper point. I have (b) a mercury
vapor arc-type nightlight in the backyard 10 feet distance from the
feedline.

Do you want it that bad?

How about simply paralleling two pieces of 75 ohm
coax for a Z0 of 37.5 ohms?

That's why a lot of 5/8WL loading coils are tapped. In the ARRL
Antenna Book, 15th edition, a 10.5 turn coil is tapped 4 turns
from the top for a 50 ohm match to a 5/8WL on 2m.

Thanks the 'trick' I use for my Field Day, 40M Vert. array.
I use two 1/4 wave, 75 ohm pieces of coax in parallel to
match the antenna to a run of 52 ohm feedline. WLAC.

>Does anyone know of a source of 35-ohm coax?

Parallel 2 pieces of 75 ohm coax.

>I want to make a 1/4 wave impedance matching line for an 80 meter
>camping antenna.

I use a 100' roll of #18 stranded wire for my 80M camping/portable dipole. I feed it various ways.
One way I have been looking at that doesn't require a tuner: Get the 100' dipole about 30'-40' up. (This is for 3.8 MHZ.) Feed it in the center with 39' of your favorite 300 ohm TV twinlead. At the far end of the twinlead, short the conductors. 3' from the shorted end, attach your 50 ohm coax (thru a balun of course).
I haven't tried this, but I will, and I am sure I am not the first to dream this up. Modelling says this should provide a 1:1 match at the design frequency. If you use 450 ohm line, it takes about 30', but 450 ohm line is bulkier.

That's *real* antenna analysis. Think about doing that
for all the wires in a missile silo to assess EMP
vulnerability and you get an idea about how the big
boys use NEC.

Actually, you can fudge it a bit. Any bump or kink
less that 1/10 wavelength in extent can be approximated
with a chord between its endpoints.

As fixed inductances in series with the "coax shield" wire.
I make your first balun to be about 10 uH, which is roughly
200 ohms at 3 MHz. Your guess is as good as mine on the
one with the rare-earth magnets. What you want to look for
is reducing the current in the "coax shield" wire to zero.

Hi Jim,

I am working on the design, however the premise appears to be
"academic." In other words, there are some who can tell you how it
should work, but not why it doesn't.

Your description above suits the modeling to a T - serious math
pushups. I don't think anyone could stumble onto a 5 band antenna by
simple cut and try.

Hi Jack,

Magnets do not play any particular role in chokes. Magnetic cores
perhaps, but being magnetic is not in and of itself a remarkable
indicator of efficient choking potential.

Research the archives for ferrites, amidon, type 43 or 75 or 77 (there
are others), beads, and so on as terms.

As for modeling them, they are resistors. You can rate them at about
a Watt to 5 Watts (I've never tested one to destruction). Again, you
need the characteristics to know how much. The typical bead exhibits
about 20 Ohms in the mid to high HF region. The shape of its curve
(the resistance vs. frequency) is variable for any particular type.
Some increase through HF, others decrease, some don't even begin until
VHF.

Beads are additive. Two beads, 40 Ohms, three beads, 60 Ohms and so
on. Passes through a larger core (same material) sees a square law
effect X1, X4, X9 and so on.

Eric,
You've essentially described a 'sleeve dipole', dont sweat it about
interaction between the copper pipe and the coax inside - though you
may wish to secure the lower end as well so it doesn't rattle around
inside the pipe. As to the use of different materials affecting
performance, shouldn't be an issue. Make sure though that you cut the
elements on the long side so you can trim to optimum length. You may
wish to do a Google search on 'sleeve dipole' and see if you find any
info that will help.

Good luck,
Howard
KE6something or other

Dave

You made a comment about the details of calculating load impedance using a slotted line. I'm curious to know if anyone has built a slotted line at home. It would be interesting to me to have a slotted line for about 125MHz.

It seems that if you could measure the voltage mins along a line terminated by the load to be evaluated and the location of the min with a short ckt to replace that load. That reading, together with the Vmax/Vmin could get you close to the load impedance with a Smith Chart (I think)

Eric

I've heard that stainless steel whips disipate a significant amount of energy ay 50 MHz. If you have several hundred watts, you might want to try transmitting with the ss whip before finalizing your design. You might be surprized to find that the whip gets warm quickly.

My EZNEC showed about 62-j114 when the radials are horizontal. BTW, Mr. Street says in his article that he got the values from a table compiled by Hallen which gives an impedance of 75-j425. Not that it matters much; it's about the same work to match either impedance.

Here is a really interesting thing I discovered while trying to verify the numbers. Make a 5/8 wave vertical with 4 horizontal 1/4 wave radials. Look at the impedance and pattern. Nice pattern, especially with an elevation at about 2 wavelengths. Now take the radials away one at a time. The resistance gets a little greater and the reactance gets a little less. With only one radial the impedance is not that bad and the azimuth pattern has become sort of elliptical. The elevation angle of maximum radiation doesn't change much, either. If the last radial is pointing to the North, the azimuth pattern is squashed slightly so that East/West is best. So the E-W gain is a bit better.

Moving down to an elevation of about 1/2 wave elevates the maximum radiation and the elevation pattern is broadened. I think, though, that it almost doesn't matter much using any of 1 to 4 radials. But the 2,3, or 4 radial patterns and impedances look very similar.

Ain't that a lick?

John

Oh, so do I. I like the antenna and rig setups, but I actually don't like the operating part of it. I pretty much just sat around last year, and let the rest of them have at it. I didn't do much as I felt unusually lazy for some reason. :/ One reason was they switched to a puter logging, keying, rig control, and all that mess, and I'd never used it before. Was clumsy as heck to me...I think I almost prefer doing it all manual...I've never liked contest type operating. To me , it's work. My idea of a better field day is sitting in a lounge chair on one of the hill country rivers, in front of a smoker, maybe sipping a cool one, "I only drink under the clinical supervision of a doctor", doing pretty much nothing at all....Maybe a casual redneck yik-yak qso every hour or so...:/ That fast contest type stuff gives me brain damage after a while. But it's hard for me to avoid being drafted, as I work CW fairly swiftly, and can rack up the points if I feel so inclined...Thats why I never work fone. It's not viable pointwise when I get half the points for fone, but work either about the same overall speed...But, I usually feel inclined to relax...A friend of mine who is also a CW op, N5XZ, he tears it up. Usually makes the most points every year I think. But he likes that type of operating more than I do. He'll stick in there a long time, where I'll usually flake out after 2-3 hours on a good year.. Just for practice, I'd like to know your numbers. I'm not qualified to coment on your info about matching the 80 meter antenna. But that three foot stub of 300 ohm line seems like it would impose alot of low impedance inductance in shunt with the feed point (50 ohm line with a 0.012 lambda, 300 ohm shorted stub across it). But, maybe thats what it takes to get the dipole from its feed point impedance to match a 50 ohm line.

Jerry

That's interesting, but in real life you're going to have a jolly time trying to make the antenna behave like the model, due to feedline radiation -- unless, of course, you've included an accurate representation of the feedline in your model. It's unfortunate, but calling one piece of wire an "antenna" and another a "feedline" doesn't make one radiate and the other not, especially when they're connected to each other and positioned so they're in the same field.

You can reduce the current conducted to the outside of the coax with a "current" or "choke" balun at the feedpoint. Induced current is another matter, and is likely to take one, two, or more additional baluns to bring to a low enough level to make the antenna behave like the nice, no-feedline model.

The radiating feedline will also have an effect on the feedpoint impedance.

Yep, that antenna will need feedline decoupling. A 2nd lower 1/4 wave
copper tube, closed at the top and grounded to the shield, and open at
the bottom like a bell, would be even better. I'd at least use a coax
choke. MK

520. Re: Question about Full Wave loop

I was contemplating putting up a full wave 160m sky wire horizontal loop. It will be kind of a square (more trapazoid actually). I was hoping to use it multi-band. I am hoping to get the corners up on metal masts up at least 50 feet.

1. Is it worth the extra trouble to get ladder line and feed into the shack (house) (as opposed to coax)? I will have pulleys so I could try one and then the other.

2. What length should I cut it for? I am new, don't particular know what frequency I might be on. I had heard that the 160m loop (approx. 540' or so) could be good as a multi-band. What exact length should I aim for, or is it even critical? 1005/?

3. If I use ladder line, I would have to use a balun in the shack to convert to coax a short run to go to my Kenwood Tuner (which has 160m), on other bands I would use a small Johnson Matchbox which lacks 160m and eliminate this balun. I am envisioning some kind of old- fashioned DPDT knife switch, I guess.

4. Actually, as a newbie, I have a nothing but more questions, like how best to override the built in relay in the Johnson Matchbox etc. I am gradually figuring this stuff out and hope to find some locals also.

5. If the ladder line proves to be problematic (there are some nearby tv cables, phone lines maybe 5-6' away at one closest point) would a coax feed to this 160m loop still be multi-band? I am not finding a consistent answer to this question anywhere online.

6. Glad to have found this board, since I am lately obsessed with putting in an antenna farm on the real estate (very big rural back yard).

7. I welcome any additions and/or corrections to my thinking so far on this loop project. At this point, I am just scrounging together the masts and pulleys etc. deciding whether to use rope or wire guys...

If you put "several hundred" watts -- let's say 300 for an example --, into a stainless steel whip, and that whip has a trifling 0.5 dB loss, the whip will be dissipating nearly 37 watts. At 1 dB loss, it'll dissipate over 77 watts. Either is likely to make the whip too hot to touch if the power is applied for long -- imagine the heat from a light bulb of that power rating coming from the antenna. If it only gets good and warm, you'll know the loss is negligible. If it gets too hot to touch, the loss could still be negligible. Unless it's glowing, you won't know for sure.

Larsen antennas has made a very good living, thank you, with their "Kulrod"(R) plated antennas by capitalizing on the irrational alarm people have when finding a warm whip antenna.

The input impedance of any 5/8ths-wave whip or rod antenna is
approximately -

R - jX = 100 - j 350 ohms.

At 29 MHz, the bottom-end loading coil consists of 10 turns wound on a 1"
diameter, 1" long former.

This and information on other antenna heights can be found by downloading in
a few seconds program BOTLOAD2 from website below and running immediately.

Jerry, if you use balanced feedline, you don't need a slotted
line. You can just use an inductive pickup loop with a 1N34A
diode rectifier circuit. Whatever you read on your DC voltmeter
as maximum and minimum values will yield the SWR. That's another
advantage of ladder-line.

Roy

I'd not 'take sides' to condem stainless steel for 50 MHz antennas. The
truth is; I dont actually know what the loss would be for a stainless steel
whip. I'd use ss if there was some compelling reason for using it. But, I
do want to alert anyone who hasnt thought fo it, that there is some loss due
to choosing ss rather than copper or aluminum.
And, I am not implying that a db is all that important. But, when someone
is designing something it is common to want to build it so the maximum
efficiency is acheived.

Zeno, In answer to some of your questions -

For multi-band working, ladder-line or preferably open wire line is almost essential.

Overall antenna length is very non-critical. When using a tuner you can be many feet adrift from the theoretical calculation without any degredation in performance. A change in length affects only the radiation pattern which for practical purposes can be considered omni-directional anyway.

For multiband operation be prepared to make relatively small changes in length of feedline as part of tuner operation.

Use a simple choke balun at the transmitter end with a balanced feedline. Make no attempt with a voltage-ratio balun to match feeder input impedance to 50 ohms. Leave that entirely to the tuner.

A choke balun for 160 meters consists of a 1.5" to 2" diameter ferrite ring wound with 8 to 12 turns of 18-gauge flexible speaker cable, or similar.

A coax feedline means lossy operation on other than the fundamental frequency.

A balanced feedline near to phone or power cables will cause no trouble unless nearly touching over a long distance.

Reg, G4FGQ

528. B&W AP-10A tuning question

Newsgroup: rec.radio.amateur.antenna
Date: 2004-04-10 09:12:43 UTC
From: jeffhs@ameritech.net
Message-ID: <98360ebb.0404100112.28fa030a@posting.google.com>
Source record: 96879

Hi.

I have a Barker & Williamson AP-10A apartment portable antenna, which I am currently using with my Icom IC-725 100-watt all-band transceiver. How do I set the counterpoise length for minimum SWR when I cannot use the SWR bridge in my antenna coupler (MFJ-949B)? I ask this because one of MFJ's technicians, in response to an email I sent the company about six months ago regarding this issue, told me in no uncertain terms that antenna couplers may not be used with the AP-10A (any mismatches are to be corrected by setting the length of the counterpoise, with the antenna connected directly to the radio). This is all well and good, but how do I know when the SWR is 1:1 if I cannot use the bridge in my coupler (by setting the antenna switch to COAX 1 DIRECT or COAX 2 DIRECT)? I suppose I could watch the power meter on the rig and experiment with the counterpoise length until I had maximum output, but I don't want to do that as it may cause unnecessary QRM. What should be my next step--to get an external SWR bridge (which has no connection whatsoever to the antenna coupler), or will tuning the counterpoise for maximum output be enough?

Thanks and 73,

Jeff Strieble, WB8NHV (mailto: jeffhs@ameritech.net)
Fairport Harbor, Ohio USA

On a table-top Broadcast Band receiver with a built-in ferrite "loop"
antenna, the antenna nulls are off the ends of the rod... correct?

In other words, all other factors being equal, the weakest signal will
result when the either end of the "rod" is pointed toward the station....
right??

Thanks,

Dave Pitzer

> antenna:> 1) Mechanically, it can be challenging. Regular Twin Lead with one of
> the wires cut is just too flimsy.

When I tried to build a working version of the Lattin, I had 2
partners. The 3 of us, collectively, have a decent amount of
experience with home-brew antennas.
Our first attempt was done using flat TV twin-lead. It was fragile
and hard to work with, mechanically. Electrically, it was just
confusing. Unpredictable. I never felt that we were close to getting
a good workable multi-band antenna.

Some time passed, and we decided to try again. This time we used the
much sturdier ladder line (for traps/radiator) as a starting point.
Mechanically, this was a fairly robust device. Electrically, it was
the same as our previous attempt. We spent a lot of time with it.
Cut up a lot of wire. We finally reluctantly gave up. We _WANTED_
it to work, but we were just not able to get anything accomplished.
Again, we felt that we were never close to having a workable, 50 ohm
coax-fed, multi-band antenna.

RE: Quote below

REALITY CHECK: a form of a normal-mode, helical radiator is commonly used for FM broadcast transmitting antennas. At their design frequencies, these elements produce the same _measured_ field strength in their directions of peak gain as produced by a matched, linear dipole in its directions of peak gain (over the same path). Some of these FM helical designs have _measured_ input SWR less than 1.15:1 over 15% RF bandwidth, which is most of the 88-108MHz FM band. For the purpose, this performance is far from being inefficient and/or narrow band.

NEC2 analysis of an FM normal-mode helix shows this, of course. Examples of it are found in the slide show (item 10) at http://rfry.org .

Reading and heeding Kraus has to take the application into account. Generalizations lead to misunderstanding.

One man's opinion:
Get it as high as you can, use balanced line & the Matchbox.

Coax has much more loss @ SWR > 1:1 than balanced line. And you will have high SWR (on the feedline) on some bands. The plastic "window" 450 ohm ladder line is OK but acts funny when wet (SWR swings). All that plastic insulation is the culprit. Moisture on the plastic causes oscillations that wreak havoc on SWR. Best to make-up your own balanced line with as few spacers between the wires as possible.

To disable the Matchbox relay, use a small bit of matchbook cover or old credit card between the relay contacts. That's what I did with mine & it's worked great for years. Very easy to revert back to the relay if you ever go to separate transmitter/receiver.

I stay away from baluns when I intend multi-band use. They don't act the same at all frequencies. The Matchbox has no balun, the transmitter output is coupled to the transmission line via a link. Also, you can extend the range of the Matchbox (to cover 160). See a "how to" article in Electic Radio Magazine -March, 2001 issue# 142, page 10. Back issues are available for $3.75 here: http://www.ermag.com/.

>Just for practice, I'd like to know your numbers.
>that three foot stub of 300 ohm line seems like it would impose alot of low impedance inductance in shunt with the feed

Sure Jerry, I was hoping someone would check it.

Eznec says at 3.8 MHZ a 100' dipole about 35' up over average ground is 17-j343. .126 lambda or 32.7' of 300 ohm line transforms to 7.5-j17.6. .011 lambda shorted stub or 2.9' connected at the 7.5-j17.6 point gives 50-j0. The .011 lambda stub is .874 uh at 3.8 MHZ . This is according to Mr. Smith and his chart.

Yes, the direct connection just bypasses the tuning components. Your
SWR meter is still functioning.

I used the ap-10 back in the 80s with my Icom 735. I seem to recall using my Bird wattmeter to measure the forward & reverse wattage as I adjusted the counterpoise length. I see no reason why you can't use the Coax 1 or 2 Direct connection on your tuner. When you do, you're bypassing the tuner's capacitors and inductor, and just measuring the feedline swr. Tune for maximum forward watts, minimum reverse watts. I used to get the reverse watts down to nothing, even on 40 meters.

I had the counterpoise wire on an empty wire spool, and simply spooled or unspooled the wire across the floor to adjust swr. I tuned at minimum power, and then increased it to maximum. If you do your tuning at minimum power, it shouldn't hurt your rig. And after awhile, you can mark the wire length for each particular band.

Watch out for a lot of rf on the counterpoise. And don't be surprised if your station is a little hot, rf-wise, as the counterpoise is transmitting indoors. Still, the little whip in the window does a surprisingly good job.

539. Homebrew dipole help please?

Newsgroup: rec.radio.amateur.antenna
Date: 2004-04-10 14:07:39 UTC
From: Bob <nubob5001@yahoo.com>
Message-ID: <SjTdc.12081$R37.5090@read1.cgocable.net>
Source record: 96890

Hi
We have put together a dipole, each leg is 66 feet. We put a 1:1 balun and it is running about 60 feet of 50 ohm coax. Presently it is about half way up the tower it is intended for so we could check the SWR before getting it up to the highest point. Presently each leg has some lags and dips, no major bends but it is just hanging there, over some bushes and the entire thing is over top of the house, and not touching anything but is very close to some steel guy wires (uninsulated).
Now we can only tune this down to a useable SWR on the 80m band. On all other bands we cannot tune it down to a safe operating range. We are using a good antenna tuner but cannot get anything useable except for 80m. Here we are able to tune the SWR right down.

Questions???
Would we be better without that balun?

Is the fact that the dipole is still too low and close to the guy wires (but not touching) our problem?

Any suggestions please??

Thank you.
Bob

If you want multi-band operation, then yes, you have to
forget the balun, or put multiple dipoles on the output lugs.

I disagree! I think it not only could happen, but probably has happened
already, through a fortuitous combination of many factors.

But being able to come up with such a design that is well-documented and
reproducible is a whole 'nother thing. The Lattin antenna is a perfect example
of that.

Source record: 96896
Cross-posted to: rec.radio.amateur.equipment,rec.radio.amateur.antenna

I have an Icom IC-RP1220 set for 1285.500 with a -12.0 input.
It's been out service for a few years, but was acting up before it was
pulled out. Now that I have time to play with it, I've noticed its
drifted 'up' 6KHz both on RX and TX, yet no chenges were made to the CPU
settings.

I have the owner's manual, but no service manual.

Is there a common xtal controlled base clock shared between the TX and
RX circuits? If so, where would the trimmer adjustment be located?

Or, if this is a problem experienced by others, and the cause is
something else, some advice would be very much appreciated!

Thanks!

Bob, the antenna as you describe it is pretty much *for* 80 meters. If
you want to tune the thing on multiple bands, and I'm assuming that you
want it for the Ham frequencies, you will want to replace the coax and
balun with ladder line, and use a tuner to match the impedence with your
radio.

One of Krause main interests was the Helix, and did the most, and best work
on it at the time.
The quote to me seems out of context, more of a comparison of "normal mode"
to what a helix can really do.
Helix is nice, great bandwidth, easy to make, easy matching.
The FM normal mode (shown in reference) is less than 2 turns, so it is being
used primarily to get circular pol.

Yep. But if the signal is strong enough, you won't see a complete null -
just a serious dip.

Hi Steven

Thank you for your response to my problem.

Any suggestion? What you say is that I would be better off without that 1:1 balun? Yes, now I have it at 66feet each leg for a total of 132 feet but now it is not at the best height but kinda sagging and lopping where it is but off the ground and about 2 feet above the roof and other obstacles. I also have it presently close to steel guy wires and the tower itself. What would be my problem then here now? You believe it is my balun? I was hoping to get this up there and then leave it. All this climbing is difficult. Do you believe that once I get it up there, with the coax, with the dipole, no balun, do you think that would allow me better results with a good antenna tuner? Any advice is greatly appreciated.

Thank you
BOb

Hi, Thank you for your response. I do not have ladder line and only have the coax basically. Is it acceptable for good results to simply use the coax and then split it out to each direction of the copper wire? And not use the 1:1 balun? I was hoping to simply get the dipole in the air and leave it and simply tune it at the transmitter to acceptable SWR and go from there. Now I only get good SWR on the 80meters because of the length it is cut at. I was hoping also to use the dipole with the tuner on 10, 15, 20 and 40. Is this possible? The tuner is good and I know I will lose the power to the tuner but would still get to use the other bands when needed.
Any more advice is greatly appreciated.
thanks
Bob

Gary

I have very little confidance in any calculations I do without outside help. Maybe you can help me. I understand the 100 foot long center fed dipole antenna is horizontal to the earth and is 35 feet up above it. At the operating frequency of 3.8 MHz, its input impedance is 17 -j343. Although I didnt realize the real part of the dipole fell that rapidly with frequency and nearness to effective ground, I assume these numbers are accurate.
I'll consider the 39 foot long shorted stub made from 300 ohm twin lead to be about 0.166 wavelength long (if the velocity of propagation for that line is 0.9). That makes the length of 300 ohm TV antenna twin lead from the antenna to the place where the 50 ohm line gets connected, to be about 0.153 lambda. And the remaining 3 feet of 300 ohm line to be 0.012 lambda long.

Would the antenna's impedance plot at 0.057 -j1.14 on a 300 ohm Smith Chart? Thats what I calculated.

If I go 0.153 lambda from the antenna along that 300 ohm line toward its shorted end, the impedance looks like 0.02+j0.18, which might be something like 6 ohms in series with 54 ohms of inductive reactance.
The three foot length of shorted twin lead seems to look like 21 ohms of inductive reactance.

I figured the impedance at the location where the 50 ohm line connects to the 300 ohm twin lead is something like 6 ohms resistive in series with 54 ohms of inductive reactance all in shunt with 21 ohms of inductive reactance.

What am I doing wrong?? The way I'm looking at the problem, there will be a serious mismatch to 50 ohms. at 3 feet from the shorted end of the "matching stub".

If I had any confidance in my thinking ability, I'd suggest using a shorter stub, so the impedance at the location where the 50 ohm line conects is still R-jX. Then the shunt L will have a chance of providing a more resistive match.

Jerry

Bob, try it without the balun. In most cases, a balun isn't needed except
to reduce TVI-type problems.

Also, if you're looking for multi-band performance, consider trimming about
30 feet off the antenna - 102 to about 120 feet tends to be more tunable.
You might also consider changing over from coax to twin lead, if you can
work the logistics...

Name one that works. And by works, is resonant in each band, and not
simply tuneable (as would be a common doublet).

>But being able to come up with such a design that is well-documented and
>reproducible is a whole 'nother thing. The Lattin antenna is a perfect example
>of that.

Hi Jim,

The notion of a trapped antenna on the basis of resonant stubs
constructions is not shown in the data of my work to date, and
certainly not in the Lattin (insofar as the only interpretation
generally available on the net, setting the patent aside that is).

One of the key points goes to this notion of stub action. However,
the stub is not excited across its mouth, but along its length. This
is very distinctly exhibited in the numbers (the lack of correlation
of stub geometry to resonances). The constructions merely appear to
fatten a thin radiator and add capacitances and inductances that are
basically opportunistic - certainly no one has shown any correlations
that fit the geometries to the bands they are presumed to resonate to.

Hence my statement that caught your fancy. The Stub resonances
"should" explain the bands obtainable, and yet there has been
absolutely no supporting evidence to demonstrate that this occurs.

It does hold my interest, however, and I am hardly one to be put off
by failure's of other's theories - not with my more than 300 pages of
fractal data published in the face of fractal fools who confine
themselves to bragging about their science.

Hi Jim,

This hard to accept given the timelines offered by those who have
reported the references. For one, the antenna was invented in the
late 40's and patented 26 Dec. 1950, and reported in 1960. ALL such
dates precede the introduction of tubular Twin Lead in the mid 60s.

I wrote, "At their design frequencies, these elements produce the same _measured_ field strength in their directions of peak gain as produced by a matched, linear dipole in its directions of peak gain (over the same path)."

To clarify this for those who didn't read through the slide show I referred to in the original post, the FM helix would need twice the input power as the linear dipole to produce the same field peak strength over the same path. The FM helix is circularly polarized; therefore its peak, net gain per polarization plane is 1/2 that of a dipole.

Most FM broadcasters in the US are licensed to radiate a certain amount of horizontally polarized "effective radiated power" (ERP) in the horizontal plane. Typically they can radiate any amount of vertically polarized power they choose, not to exceed their h-pol ERP.

The station's ERP is the product of the tx output power, the efficiencies of their transmission line, channel combiners, filters etc, and their antenna gain, per polarization. Using a c-pol antenna means that the broadcast station needs twice the tx output power to produce their licensed h-plane, h-pol ERP.

Hi Bill,

Your response hardly carries the water for an argument supporting gain being commonly distinct from directivity.

To answer Jerry's question (he probably already knows how) requires the total integration of all power emitted by the radiator - not an easy task (as would confirm Bill's sparse reply) and then measuring power emitted within small volumes (solid angles of sub-radian dimension) to compare against the whole.

The most distinctive point to observe about this "gain" is that almost all the power radiated is lost - "almost" being a patronizing term. A simple thought problem will reveal this sad fate.

Let us presume you are transmitting 100W with 100% efficiency. Now, lets further presume that the entire population of the planet is monitoring you with S-9 readability. That is (let's be generous), 10 Billion receivers. What is the net result of this massive communication in system efficiency?
0.5%

The antenna in the most perfect of circumstances exhibits an absolute loss of 99.5W and I could easily bet no one here even pretends to approach 0.000001% of this.

Now, tell me about GAIN. :-)

If this is a real problem, it can be solved with an antenna analyzer
like the MFJ-259B, one of the handiest devices I have ever owned.
Got any friends with one?

You can also reduce the power out of your IC-725 to the absolute
minimum value, ID yourself, and experiment until you get it right.
At minimum power output, I doubt that any damage would be done.

The antenna is a non-resonant length on most of the other HF bands. You
cannot afford the SWR power loss when feeding it with coax on any band except
80m. Take a look on my web page how I solved the all-HF-band problem using
essentially the same type of dipole. You need to feed such an antenna with
twinlead, window-line, ladder-line, or open-wire line. That moves the balun
to the hamshack. 100 ft. of ladder-line is close to optimum.

> Is the fact that the dipole is still too low and close to the guy wires (

That may be part of your problem but not the biggest part.

Just to make sure we are on the same page here: are you saying to use this choke balun just for operation on 160m if I want to use my Kenwood tuner? I am assuming that when using the Johnson Matchbox for the bands it was designed for I would connect the feed line directly to the Matchbox terminals, and that feedline would connect directly to the antenna (no baluns, no chokes, or anything).

Feeding your dipole with ladder-line moves all the matching problems to the
hamshack where you don't have to climb anything to solve them. Try the following
configuration and get back to us on any remaining problems.

XMTR--tuner--1:1 balun/choke--100 ft. 450 ohm ladder-line---132 ft. dipole

This configuration will allow multi-band operation on most of the HF ham
bands. The problems you will have with a couple of bands are solvable.

The coax *IS* the problem. If you don't like to climb, you are going to
have to replace the coax with something like 450 ohm ladder-line. 100
ft. of such ladder-line costs about $17.

One other possible solution is to install an autotuner at the antenna
feedpoint but that is a pain to do.

Do you have any pointers or good recipes for making my own balanced line? materials, spacing, wire size, insulated vs. bare, etc. never done this before. Also I will have to go through approx. 1+" of wood at the peak of my house, and then again about 1" of wood to come down through the old farmhouse ceiling directly to the station. This balanced line will be travelling about 12 feet or so through my attic and fortunately there is not metal or wiring in that area to speak of.

In the olden days, 1985, on an outdoor range, we would calculate the gain from measuring the 1/2 power points on an antenna range at 1000 wavelengths minimum between antennas and find the 1/2 power [-3 dB] angles in the horizontal and vertical planes. [Note C-Band and S-Band]

Knowing the angles the 'Gain' is calculated by dividing 41259 by the product of the horizontal and vertical angles corresponding to the 1/2 power point. [Note: 41259 is the surface of the sphere measured in square steradians.]

On the indoor anechoic chamber we measured the input power at the feed point through a -10 dB splitter and the radiated power density at a target point in the far wall. Then ran the basic calculation. [Classified Military Program]

Aligning those 12 foot diameter dishes inside the anechoic chamber was 'fun'.

Even after managing two antenna ranges and being party to 'antenna gain' measurements for more than 10 years of my professional life, I still have fun touting that antennas have 'No Gain'.

The claims of the QST article are that the stubs work as traps. It also
explains that the velocity factor is important in the whole design. The article
refers repeatedly to "tubular Twin Lead" as the optimum material for
construction because of its velocity factor of 0.8.

>Would we be better without that balun?
>
No.

>Is the fact that the dipole is still too low and close to the guy wires (
>but not touching) our problem?

No.

> Any suggestions please??

The problem is this:

The antenna you describe is approximately:

one half-wavelength long on 80 meters

two half-wavelengths long on 40 meters

four half-wavelengths long on 20 meters

six half-wavelengths long on 15 meters

etc.

Such a center-fed dipole antenna has a feed point impedance that is fairly
"low" (that is, under about 100 ohms) on frequencies where it is an *odd*
number of half-wavelengths. On frequencies where it is an *even* number of half

wavelengths, the feed point impedance is very high - greater than 1000 ohms.

The 1:1 balun and 50 ohm coax you are using are low-impedance devices, so they work fine on 80 meters. But on the other bands, they do not work with the high impedance of the antenna. A tuner at the shack end of the coax cannot make up for the enormous mismatch at the antenna end. Even if it could, the loss in the coax from being operated at such a high SWR would make such a system very inefficient.

There are several possible solutions:

1) Use a different transmission line (high impedance balanced line) and eliminate the balun. This requires a balanced antenna tuner and the mechanical difficulties of using non-coax transmission lines

2) Use a different sort of dipole that is an odd number of half-wavelengths on the desired bands. One form of this dipole is the "trap dipole", in which tuned circuits (traps) electrically alter the effective antenna length.

A really good information source is W4RNL's (Cebik) website. Goole on his name or call to find it.

> Chart? Thats what I calculated.

Nope, 29.5 feet (0.127 lambda) around the 300 ohm SWR circle from the 17-j343 antenna, the impedance will be 7-j17 without the stub. In parallel terms, that is 48 ohms in parallel with 2000 pf (~21 ohms). Neutralize the 2000 pf with an inductive stub and you have a feedpoint impedance of 48 ohms. You seem to need about one microhenry for that. Matching can be accomplished with a coil instead of a shorted stub.

IMO, a better way would be to extend the feedline to 33.8 feet (0.145 lambda) where the impedance is the conjugate of the above, about 7+j17, and a capacitive stub will cause the match to 48 ohms. Or a parallel cap of about 0.002 uf will accomplish the same thing.

These matching methods make use of the 1/50 conductance circles on the Smith Chart. These easy matching methods will work for any SWR greater than Z0/50, i.e. for Z0=300, for any SWR above 6:1. At the point where the SWR circle crosses the 1/50 conductance circle, simply install an appropriate parallel inductance or parallel capacitance and it twists the impedance at that point to 50 ohms (48 ohms above). Since that is also a voltage minimum point, relatively cheap low voltage capacitors can be used, e.g. 600v micas.

Mike, unless Bob does both, trim to 102 ft *AND* use twin-lead, That is
very bad advice. A coax-fed 102 ft. dipole is resonant on 4.59 MHz
which is not inside any ham band. It will be a terrible performer
on all HF ham bands except 20m where it will have an SWR about 3:1.

> That's quite understandable, given that the original Lattin designed used
> tubular Twin Lead and countd on a velocity factor of 0.8.

Yes...we were aware of the differences in velocity factor. And now I have dug up more notes from those experiments. I had forgotten about a _THIRD_ atempt!! We also tried using heavy 2-conductor speaker wire as trap/radiator material. This was also a sturdy design, mechanically. And again, we took into account the different v. factor.

But it didn't produce the antenna we had hoped for.

>>> What sort of test gear and design methods did you folks use?

Pretty fundamental test equipment. The ordinary items that are in just about all shacks. We did have a good SWR meter.....a Siltronix FS-310. We also had a good grid dipper, the military AN-PRM/10 unit. There was also a Palomar Noise bridge in my possession during that era, but I don't see anything in my notes that indicate that we used it in our Lattin experiments.

We cut it longer, and we cut it shorter. We diddled with the traps _IN_ the circuit, and we diddled with 'em removed from the circuit. We used up a lot of wire, and a lot of notebook paper.

This was back in 1990 and 91. I still wonder what we would have accomplished if we had owned an Antenna Analyzer? And what if 1 or more of our trio was fleunt in antenna computer modelling? Would we have "cracked the nut"......or would we have just wasted more wire, paper, and time? We never once felt that we were close to getting a good multiband antenna. We sure tried, though. It was kinda fun, really........

Hello again!

Direct quotes from the 1960 QST article:

"If open line with a velocity factor near unity is used for the stubs, the over-all lenght for a two-band antenna would be nearly a full free-space wavelength at the higher frequency and and the whole antenna would resonate at something less than half that frequency. Very fortunately, the the velocity factor of 300-ohm tubular Twin-Lead (0.8) gives such lenghts for the stubs that that, in most cases, the adding the stub makes the antenna resonate at just half the original frequency."

"Fig. 3 shows how tubular Twin-Lead can be used for the antenna itself as well as the stubs and includes dimensions for 10- and 20-meter operation. The foam-filled type of Twin-Lead is recommended to keep out moisture."

So it must have existed when W4JRW wrote the article, some time before the December 1960 QST went to press.

In addition, my 1953-54 RESCO (Radio Electronic Service Company, once a great source of all things radio and TV here in the Philly area) catalog lists Amphenol "flat and tubular Twin Lead". The tubular stuff is number 14-271 and was 5 cents a foot - less in quantities of 100, 500 or 1000 feet. And it wasn't a new item.

All of this supports both your experiences and those of others. If the exact characteristics of tubular Twin Lead are important to the design, it's no wonder that the reported results cannot be obtained.

One more point. The SWR graphs shown for the 5 band version show quite narrow SWR bandwidths. If anyone is interested I can report them in a future post.

That's OK, High Q loading coils are not necessairily bad things at
all. A couple decent-size airwound coils are *much* easier to come by
in the shack than they are up in the air and out in the weather. Plus
you can vary the L right in the shack.

I'm not far enough along my modeling learning curve to be able to
model transmission lines yet but you're obviously right.

Assuming some full system modeling of the Boyle Special for basic
guidance, the availability of a 259B, another ceramic rotary switch
and a pile of silver mica caps what are the downsides of using fixed
caps vs. variable caps?

Jim, I haven't been following very closely. Is it possible to describe
this antenna with an ASCII diagram. Apparently on one band, the stub
is installed at the 1/50 conductance circle to SWR circle intersection.

might
> have to change length of feedline? I am trying to picture that, is there
some
> convenient solution to this process?

No, it is not necessary to change length of feedline for each band. Far from
it.

The tuner will allow you to cover most bands with one length of feedline. If
you are very lucky you may be able to cover all bands with one length of
feedline. No two antennas are alike - and it is just a matter of luck.

You will probably find that, initially, 2 or perhaps 3 bands are difficult
to tune using the tuner. By changing feedline length, up or down, you may be
able to reduce the number of awkward bands to 2 or 1 or perhaps none. As
length is changed some bands will get worse and others will get better.

It is always possible to find a length of feeder which will allow the tuner
to cope with ONE particular awkward band. It is a matter of experimenting
to find a length which maximises the number of bands which can be
accommodated by the tuner.

Hardly anybody is interested in ALL bands. Naturally, you will include your
favourite bands amongst the best. Some tuners are better than others.

Leave the 1-to-1 choke balun in circuit all the time, for all bands, and for
whatever tuner you are using.

The sort of problems you will encounter are exactly the same as getting the
G5RV to work on all bands by choosing an optimum length of feedline.

That would probably be the way to go. I'm big on keeping
dedicated-purpose tuners like this one would be out in yard right at
the end of the feedline instead of in the shack. Relays would work
fine and are easy to remotely control.

> >A
> >tuner like that would be a whole bunch easier to build and use and

I don't see any particular point to using continuously variable coils
and/or caps when the same job can be done with their much more
reliable and simpler fixed value eqivalents in situations like this.
High parts counts and moving widgets in any combination is trouble
looking for a place to start.

>Matching can be accomplished with a coil instead
>of a shorted stub.

Thanks for explaining this matching technique in slightly different terms that people may be more comfy with. I was trying to keep the parts count down since this is a camping antenna. Using one 300 ohm line of correct length, shorting the end, and tapping at the 50 ohm spot seemed pretty simple. Or as you state, use the conjugate method and leave the line open and tap for 50 ohms.
>These matching methods make use of the 1/50 conductance circles on the Smith
>Chart. These easy matching methods will work for any SWR greater than Z0/50,
>i.e. for Z0=300, for any SWR above 6:1. At the point where the SWR circle crosses the 1/50 conductance circle, simply install an appropriate parallel
>inductance or parallel capacitance and it twists the impedance at that point
>to 50 ohms (48 ohms above).

I didn't know I was doing all that! Thanks for the info.

Source record: 96829

It should be added, the reason for changing feedline length is to bring its input impedances on the various bands into ballparks which can be accommodated by the tuner. Ideally, input impedances should not be VERY much different from 50 ohms. SWR not much worse than 1.5 or 2-to-1.

The line behaves as a different impedance transformer on every band. It is a random adjusting process.

In principle, with a perfect tuner, ANY line length would be satisfactory.

W2QHH, for one...;-)

Here's my main point in all this:

Whenever antennas are discussed, you will often see descriptions such as "we did really well" or "outstanding performance" or some such. Particularly FD antennas.

But what constitutes "outstanding performance" is usually not defined. For some folks, making 10-15 QSOs per hour on FD when the band is wide open is "outstanding performance". For others, making 2-3 times that rate under similar conditions isn't "outstanding performance".

Patterns and simulations and SWR curves on websites are great stuff, but what really matters to me in terms of "outstanding antenna performance" on FD is how many QSOs you have in the log when it's all done.

The balun is basically what is limiting your multi-band
operation. At crazy impedances the balun
prevents the shield of the coax from assisting in absorbing
some of the mismatch. Others have pointed out that the
optimum situation is to feed your antenna with balanced line...
if you must use coax, and you must have multi-band operation,
then use an antenna tuner without a balun upstairs. RG58
doesn't work nearly as good as RG8... I couldn't make my
inverted vee (resonant at 3750kHz) work 15m until I switched
over to RG8. You should avoid legal-limit operation on the
higher bands with this setup, unless you like burnt coax.

> I was hoping to get
> this up there and then leave it. All this climbing is difficult. Do you
> believe that once I get it up there, with the coax, with the dipole, no
> balun, do you think that would allow me better results with a good antenna
> tuner? Any advice is greatly appreciated.

Yes, the good antenna tuner is the key. Get one
with a built-in balun, so you can try balanced feedline
when you get a chance. It really is hotter, both listening
and transmitting.

You should only climb once, put up a yardarm, rope,
and pulley, and then you can play to your heart's content.
Mounting a wire antenna permanently is pure hubris,
beware!

Hi Jim,

I stand corrected on the tubular twin lead (must've died in the
mid-60s then).

It offers nothing substantially different to the physics of design
however, just a different velocity factor which is scalable to suit
any implementation.

However, my data to this point confounds the "theory" of it all by
exhibiting stubs that do NOT resonate at their computed length
(complete with correction for ANY velocity factor commonly observed).

More data is always appreciated.

> Any more advice is greatly appreciated.
> thanks
> Bob

The 1:1 balun isn't effecting the match on the other bands. If you
remove it, there probably wouldn't be much difference at all.

You could maybe put traps on the antenna so that it will be able to
resonate on multiple bands.

Another option would be to make multiple dipoles for the other bands.
The impedance mismatch will make the signal tend to go down the dipole
that corresponds to the desired band. Think of that sort of dipole as a
fan so to speak. If you go this route, You'll want to trim the lowest
band first, then work your way up in frequency for the other parts of
the dipole.

But all of these options are a good deal more work than the ladder line
method. But if you won't or can't use ladder line due to your
circumstances, I'd try the fan dipole.

Lattin seemed to think it was important. Do you have the 1960 QST article?

>However, my data to this point confounds the "theory" of it all by
>exhibiting stubs that do NOT resonate at their computed length
>(complete with correction for ANY velocity factor commonly observed).
>
>More data is always appreciated.
>

Well, here's the info from the 1960 QST article.

Dipole dimensions:

Innermost section (not a stub; shorted at both ends): 8'
Next section (stub; open at inner end): 6' 11" [resonant at 10 meters?]
Next section (stub, open at inner end): 13' 10" [resonant at 20 meters?]
Outermost section (stub, open at inner end): 27' 5" [resonant at 40 meters?]

Entire antenna 57' 2" per side (plus connections)

SWR, 50 ohm coax, coax length not given (all numbers guesstimated from graph):

80 meters:
Minimum SWR: 3725 kHz - 1.1:1
2:1 SWR points: 3625 & 3800 kHz (175 kHz)
SWR at 3500: 5:1
SWR at 4000: 4.5:1

40 meters:
Minimum SWR: 7225 kHz - 1.6:1
2:1 SWR points: 7150 & 7275 kHz (125 kHz)
SWR at 7000: Off end of scale (5:1 at 7075 kHz)
SWR at 7300: 3:1

20 meters:
Minimum SWR: 14250 kHz - 1.3:1
2:1 SWR points: 14100 & 14375 kHz (275 kHz)
SWR at 14000: 3.5:1
SWR at 14350: 1.8:1

10 meters:
Minimum SWR: 28600 - 1.6:1
2:1 SWR points: 28500 & 28750 kHz (250 kHz)
SWR at 28900: 3:1

Chart for 10 meters covers 28500 to 28900 only. No chart for 15 meters but text says it will work there on 3/2 wavelength resonance of 40 meter section and SWR of not less than 3:1.

Note how tight the 2:1 SWR points are, even on the higher bands.

--

Also described is an 80/40 dipole. Inner section is 28' and shorted both ends, outer stub section is 27' 5". Interesting feature of this one is that in order to achieve 40 meter resonance there are pieces of wire 2' 6" long hung from the junction of the two sections. The text and diagram say the outer section resonates on 40 but the inner section has to be kept at 28 feet or the 80 meter resonance will be too low.

--

Seems to me that the classic W3DZZ trap dipole would be a lot less aggravation to model and get working, plus more flexible in choice of minimum SWR points. Particularly if additional "resonance wires" were added if needed. Certainly easier to make mechanically strong traps than stubs, and adjusting single wire lengths with Burndys is a lot easier than fooling with tubular Twin-Lead.

Steve,
I don't know what a Fairhaven RD500 is. However, to hear the services you want on HF, you need a radio with Single Sideband capability, and an IF bandwidth of no more than 3 KHz.

Assuming the above is true, as a *first approximation* the longer the wire and the higher up the better. A 100 foot wire, center fed with coax, and 50 feet up works quite well.

A very complete book (4 volumes), with both theory and practical information, is Lee & Lo, _Antenna Handbook_. It should be in print. For theory, one I particularly like for clarity and insight is King, Mimno, and Wing, _Transmission Lines, Antennas, and Wave Guides_. There's a 1965 Dover paperback reprinting of the 1945 original, that's pretty easy to come by. Another theory book is Jordan and Balmain, _Electromagnetic Waves and Radiating Systems_. And if you really like math and want to get at some fundamentals, try King and Harrison, _Antennas and Waves_. (It'll give you an appreciation for the subtle complexity of even a humble dipole, and a real appreciation for today's modeling programs.) I'm quite sure that all but Lee and Lo are out of print, but it's getting pretty easy to find older books on the web. Amazon has a deal with a lot of small dealers, so you can order older books from Amazon -- I just got a 1965 book on numerical methods from a bookstore in Colorado that I ordered through Amazon.

If you really want to dig into antenna theory, you're really studying electromagnetics. There are a number of good textbooks in that field, also.

Hey Guys,
I have the original article here. If you want it I can scan it and
send it to those requesting.

This has become an interesting thread. I went through hell with mine,
using flat twin lead and not knowing the velocity factor. I had pieces of wire
hanging from the ends of each trap to try and 'trim' them. I also had the problem
of support -- strung a string through the line through holes poked in the twinlead
with a soldering pencil. It came close, but it was quite a while ago. I mentioned
Bob, VE6TE (now SK) who had the full model -- probably the tubular twin lead too --
he never threw anything away! The tubular was a precursor to foam filled (I would
imagine).

If I were ever to go near this antenna again, I'd build a two band model which
might be simpler, and of course now I have a MFJ-259B which might help a bit. It
lies rolled up in a corner of the shack gathering dust -- I had so much hell with it
that I'm reluctant to ever look at it again. One alternative would be to make a
vertical model operating against a good ground -- it would be simpler!

The only reason I built it was because of VE6TE -- and my desire to find the
'ultimate' cheap and simple multiband antenna! Dream on!

I have no doubt that this is the place to go if you're a hardcore radio fan.

I started reading this group in hopes of finding out how to pick a better antenna for my RadioLabs-modded Sangean 909, but have to admit that I've come away more confused than ever.

To keep my needs simple, I need an external antenna for a wide range of bands (between 150 and 30K KHz) that mates with my RCA jacks. I've read about the benefits (or necessity) of a separate antenna tuner, and some brands have come up. I've heard about the Sony AN-1, but found that it's discontinued and Ebay may be the only source, and there are some other loop antennas that I cold lay out on my roof...but I guess I don't know what's best.

What thrills me about listening to my radio is picking up signals from all over the world, finding out what other people think and say. It was always cool to me, even when I was a little kid and sat around an old Sony FY-410 worldband radio (which I still have, and it still picks up plenty nearly 40 years later). I don't plan to ever transmit--it's a passive sport for me--and I live in Central New Jersey (USA) so there's plenty of noise to compete with.

So, can you hook a brother up? LOL

"Antenna Theory" by Constantine A. Balanis is pretty good - good
enough for me to have it. :-)

598. long wires around the farm

Newsgroup: rec.radio.amateur.antenna
Date: 2004-04-11 03:53:49 UTC
From: Dan Jacobson <jidanni@jidanni.org>
Message-ID: <878yh3gofm.fsf@jidanni.org>
Source record: 96812

http://www.hard-core-dx.com/nordicdx/antenna/wire/beverage/view1.html
got me thinking about all those long AC wires to the pumps on the
farm. When not in use they could instead be used as antennas, eh?
One would use a double knife switch of course to make sure AC would
supposedly never get to our transceiver.

Say, would water in long plastic pipes count as an antenna? I suppose
it would have to be rather impure water.

After re-reading the manual (and an hour or two of net surfing) it turns out the reference frequency is tweakable via the TT remote command set. More than ample adjustment to get it spot on.

(...I really have to learn to not read manuals when I'm over-tired. It was there in a table. No reference to the feature in the manual, but it was listed as a command none the less...)

Thanks to all who read my original post.

Pat

I've got two and three band models right now. Just not the right
bands is all.

That's exactly how I start. It gives me a faster running model so I
can go through the iterations quicker.

My recommendation is a random wire with a coax transmission line. Use
75 ohm "cable tv coax" as impedence isn't an issue, the loss is as
minimal as RG-8 type cable and you can't beat the availability & cost
Radio Shack sells an 'F' to phono plug adapter if you don't want to
fiddle with soldering the phno plug to the coax. For a proven method
of how to minimize noise the following article is a 'must read':
http://www.anarc.org/naswa/badx/antennas/low-noise_antenna.html

You will find many other useful ideas if you browse many of the
articles on the 'parent' site http://dxworld.com/dxnews.html#ANT and
then for even more info on shortwave, and broadcast band monitoring,
the 'grandparent' site http://www.cybercomm.net/~slapshot/speedx.html
is highly recommended.

As to the tuner, or preselector - different animals though some use
the terminology interchangeably, I'd hold off on worrying about using
one. A tuner matches the impedence of the antenna to that of the
radio, whereas a preselector works as a bandpass where it rejects

signals outside the frequency where it is tuned. First order of business is to get the antenna installed, pay attention to grounding, keeping the antenna clear of powerlines (can be hard in a city, if possible run the antenna perpendicular to the power lines, it can help to reduce noise) and when routing the cable into your home keep it as clear of the household wiring as possible.

There ya go, all "hooked up"

Howard

Buy the cheapest Ham radio antenna tuner (especially without meters
you don't need). Used is OK (as long as it isn't burned out).

>, and there are some other loop
>antennas that I cold lay out on my roof...but I guess I don't know what's

A long wire as high as you can get it will fill your bands. A loop
may be more useful for AM DX.

Hi OM,

For that anticipated noise: search the archives of this group for
"chokes" for antennas, also use keywords like "ferrite" and "1:1
Balun."

> Outermost section (stub, open at inner end): 27' 5" [resonant at 40 meters?]

Is this just an attempt at a trapped antenna using stubs for traps?
It doesn't seem to model out to be very functional. The outermost
stub on 40m needs to have a very high impedance, i.e. 1/4WL shorted.
That works well to resonate the vertical on 40m, but 1/8WL on 80m
makes the antenna resonant at 3 MHz according to EZNEC.

Hi Bill,

My first assignment out of Metrology school was in Charleston S. C.
loaned to the SeaBees (because my ship was still in Rota Spain). They
took full stock of my million dollar training and found I was
qualified to dig ditches in the clay banks along the Charles river.
They were impressed I knew which end of the shovel went into the
ground and we became fast friends (made me an honorary SeaBee).

Navy motto, "those that work hard together, play hard together" (I
had already learned that from my Pig-boat buddies.)

Hi all

I have it back up without the balun, and still have to use the coax for now. I am able to tune it now on all bands but I am sure there is a lot of power loss from the tuner. I grounded out all devices in the shack but still receiving a lot of RF interferrence on tv, computer, and home alarm.
Thanks for all the advice, really appreciate it.

Hi Bob,

Unfortunately you have proven that the BalUn was very effective in
doing what it is designed to do - prevent all the problems you have
now inherited from those who blamed your coax.

Mikes suggestion was the best - fix the antenna. The golden rule of
consulting is to give the customer advice they can perform. You are
limited to coax and they all had twin lead answers. Mike's suggestion
of making multiple dipoles AKA fan dipole is the simplest and quickest
(just make sure that you drop the ends away from each run by one to
two feet - the fan).

This is the approach that I'm taking,
6 and 20m dipoles up now with balun, and more as I have time/inclination.

Me, I like the antenna to do the radiating, not the feedline.

Bill

First - I want to be clear that I have absolutely no problem with using
the term GAIN for describing antenna performance.
I did think had not been established, in this thread, that an antena's
gain has to be referanced to some standard antenna, like a dipole or
theoretical radiator like 'isotropic'. I'd submit that, what we refer to as
antenna gain could be more accurately be called 'specific gain'. I also
tink that the term Directivity clears up any misunderstanding about what can
be done to improve an antenna's performance. And, I realize that my
thinking about Gain and about Directivity dont imply that anyone needs to
exclude either from their vocabulary

I suspect my caution about antenna gain stems from reading specs that
display extremely high "gain" numbers while the antennas are actually quite
ordinary.

Absolutely. Whenever I see a gain number that dosen't reference something,
I assume they mean dBi, rather than dBd.

Not a problem with a balanced antenna and a current
balanced feedline.

I've seen a few antennas that should be spec'd as negative dBdl. :)

Hi there,

Anyone have one of these? Ive just bought one with no manual. What aux antenna should I be using and where should the aux antenna be located in relation to my main antenna.

Secondly, what is the procedure for tuning the gain,phase1 and phase2 controls.

Mnay thanks, John G0WPA

Actually the first to suggest the multiple-dipole approach was Steve KI5YG,
and that should indeed work extremely well, bearing in mind that the lowest
dipole should still maintain an angle from leg-to-leg of greater than 120
degrees, if possible. I use just one "fan" under the main resonant frequency
(around 60 meters), and it is also resonant at the tuned length of the
"fan", or second dipole as well. Using the tuner works very well up to the
required 15mhz range that my particular station requires. "Very well" to me
means that bareback testing is receivable from a station in Caracas,
Venezuela, which is over 2,000nm away.

Hi there,

I had a Sangean type Roberts RC818 as my first radio, that was a great performer.

For HF listening, you cant beat a longwire!! Run the wire as long and as high as you can! Match it to the receiver using either a cheap RX only ATU or a Magnetic Longwire Balun ($ 25-ish). There is NO NEED for active antennas, there is so much signal on HF, and your receiver is sensitive enough to work with a little telescopic. A properly matched long wire will haul the signals in...

John.

Hi Jerry, I need to apologize to you. I realize now that your 0.057
-j1.14 figure is a value *normalized* to 300 ohms. 17-j343 is indeed
0.057-j1.14 when normalized to 300 ohms. Sorry about the misunderstanding.
Guess I'm getting senile.

I just swept a Drake TV-1000-LP and Bud Variable Low-Pass Filter #LF-601 using an HP 8443 and HP141T with a 8552B and 8553B. The Drake goes from 0 dB at 51.3 MHz and drops to -50 dB at 57.1 MHz. While adjusting the Bud it was kind of neat to watch the impact of each of the 5 varaible capacitors in real time I got 0 dB at 41.7 MHz and 60 dB attenuation at 54.5 Mhz. I didn't try to optimize the Bud for channel 2 as yet, that's next. I'm guessing I'll lose the extra 10 dB attenuation the Bud provides but maybe I'll get a sharper knee after I optimize it for channel 2 attenutation. My question is what happens to the attenuated energy that the low pass blocks as there are no resistors in either? I'm sure I'll see some surprises as soon as I sweep both with my return loss bridge as soon as I find it.
Tnx

Hi Jerry and Cecil, When I did my plots it was with a 50 ohm chart. I must confess I use a Smith Chart program that lets you plot any impedance on the normalized 50 ohm chart, with correct results. The program prompts when using Lines, Impedance=? Having been spoiled by the computer, I never really considered plotting transmission line Impedances on a Smith Chart that were different from the normalized Impedance.
This is a neat little free demo program I use. Maybe I need to get back to basics.

Just curious, George! Because antennas at that frequency are relatively small to begin with, I've never considered loading anything like that. I'm curious as to why you would want to -- there must be a good reason, isn't there?

If you use a Magnetic Longwire Balun, ANY length of wire should present roughly 50 ohms to the receiver. The amount of extra signal will be considerable! I used 33 feet of wire with a Roberts RC818 some years ago, which worked really well, but when I added the MLB, there was a vast improvement. These MLBs have a PL259(actually SO239) connection at one end and a wing nut for your longwire at the other end. Hayden, W&S, and Maplin all supply them here in the UK for about ï¿½20. A worthwhile investment for the terminally lazy! Otherwise, an ATU is perhaps a better option, except that browsing a band will require constant retuning of the ATU. Personally Id suggest an ATU over an MLB because there will be attenuation of off freq signals that may otherwise cause you problems. So theres your choice! If you want some help building an ATU or sourcing parts, E-mail me, but take QRM off my e-mail addy, :) ...John.

634. screwdriver tuneing 2m ?

Newsgroup: rec.radio.amateur.antenna

Hi there,

Ive answered your other posting, Homemade Antenae help re: ATUs and Magnetic Longwire Baluns etc. As for frequencies, try this site....
http://www.ajpotts.fsnet.co.uk/links.html
its packet with HF military, marine, civil air and Amateur band frequencies. A copy of Shortwave Magazine is a great read every month(WH smiths), they have HF utility stuff and wierd stuff like Maritime beacon listening, Numbers stations and propaganda stuff, its all good fun...
John, G0WPA, Bournemouth.

Having given my Ham callsign, id better make it clear that listening to ANYTHING except Terry Wogan radio2 is illegal, :) and up 2 you. mail me if I can be of any help....

William J. Lattin was awarded patent # 2,535,298 on Dec 26, 1950.
This was a patent for the recently discussed "Lattin Antenna".

I have a photocopy of that patent in my possession.

However, when I go to the website of the US Patent Office, I'm not computer geeky enough to be able to wade thru the extraneous government fluff and see his patent.

Here is the URL of the Patent Office:

http://www.uspto.gov/index.html

Has anyone else had any luck accessing Mr. Lattins patent at the Patent Office website?

Yep, there is. I'm designing a very small hand-held antenna for direction finding. The smaller the better. On paper so far I have shortened "half-wave" dipole elements to 0.32 lambda and am giving up 1 dB of gain in the process, assuming the coils I mentioned in each side of the dipoles.

Now the question becomes, is it practical and buildable?

BTW, congrats on your numbers! I, too, have seen a big improvement in my own cholesterol numbers as a result of diet and exercise, not to mention overall fitness ... :o)))

Looking up other patents, I know that they do not have all patents
before a certain date actually online in text form.

The older method was to go to either the main Patent office in DC, or
one of the 10 repositories in certain city libraries around the
country, where they have hard copies or microfiche of the older
patents, (now combined with access to the online resources). For
example, for New England, they are at the Boston Public Library's main
branch in Copley Square.

I looked up that one in a patent number search, and they do not have
it in text form, only in image form. I saw the 4 pages. They are in
some QuickTime readable format, so check that you have the free
software installed. To print you need to install very specific
software detailed in their FAQ.

This URL may help you find the specific patent:
<http://patimg2.uspto.gov/.piw?Docid=02535298&homeurl=http%3A%2F%2Fpatft.uspto.gov%2Fnetacgi%2Fnph-Parser%3FSect1%3DPTO1%2526Sect2%3DHITOFF%2526d%3DPALL%2526p%3D1%2526u%3D%2Fnetahtml%2Fsrchnum.htm%2526r%3D1%2526f%3DG%2526l%3D50%2526s1%3D2,535,298.WKU.%2526OS%3DPN%2F2,535,298%2526RS%3DPN%2F2,535,298&PageNum=&Rtype=&SectionNum=&idkey=4641AA8514F7>

Hi Henry,

Returned to sender - postage due (the source pays the penalty).

It never even makes it into the filter (such is the success of its
design). The mismatch could cause an arc over at the input port, but
then you have one nasty mis-behavin' transmitter (which is one very
good reason to use filters). The sense of "attenuation" is not so
much that the filter grinds down the rough edges, it is more that it
didn't fit through.

Hi Lee,

Yup, as Gary suggests, it requires a patent number search. Inventor
names and other sorts do not work because patents before 1976 are
stored as images.

As I reported elsewhere, the patent and the web available rendition
are two very different tunes.

That feature seems to be a common characteristic of Japanese manuals. I repaired a Kenwood 440 for a friend. Looked all over for instructions of how to set up one of the oscillators. Not mentioned in the index or anywhere in the text. Appeared as a note on the schematic. Only took a couple of extra hours to find it. Same manual lists every metric screw, nut and washer in painful detail. Why?

The newer editions of that book (at least from the third edition) are edited by Richard C. Johnson. It's an excellent reference, but I didn't include it in my recommendations because Al specifically asked for books on antenna theory. Jasik/Johnson has a lot of qualitative explanation of antenna operation and a wealth of practical information for making antennas, but I wouldn't characterize it as one that goes very deeply into antenna theory. It does, though, have a very good treatment of phased arrays of a few elements that you won't find many other places. I do recommend it for any antenna library, but not as a source of fundamental antenna theory.

Stolen from 100 Ironwood Drive in Las Vegas, Nevada sometime between
April 10 and April 11, 2004:

Two sections Rohn 25G Tower
One Rohn 25G Top section
One Rohn Roof/Eve Mount

One Hy-Gain TH7-DX 10/15/20 Triband HF Beam

One Ham-IV Rotor

Two homemade sloper antennas

One 440MHz business band Yagi

All of this equipment was formerly owned by Alan Foster, KB7UI and
disassembled and purchased by Jason Creager, KC0ERG, before Al moved
to Yuma, Arizona this weekend.

There are several items missing from the complete package, so if you
hear of anything being "parted out" and think "That's odd. Why is THAT
missing?" please contact me as I can identify all of the stolen items
. If you know the whereabouts of this antenna, please contact me at:

StolenTower@cox.net

I'm really hoping that this was an honest mistake and that someone
picked up the gear from the hiding spot at the house to keep it from
being accidentally thrown away.

Please forward this message (in a nonannoying method :-) to any mail
reflectors for ham organizations in the Western United States.

Thanks very much,
Jason

Thanks for the correction on "Jasik", my fingers get dyslectic.
I agree with Roy below, it is like a survey book, not as deep math wise as it could go, then some good sections. Usally It or Krause have something on an antenna.
Krause has another "book" out, on astromonical antennas, (about 1958?) not a hardback, and was sold in the back of Sky and Telescope magazine a few years ago. Excellent book, I cant find it right now, I think it was Astrominical Antennas, some discussion of the giant antennas he built on campus. Not amateur radio stuff.

I would like to find a good antenna book on Log periodic below 1 GHz. I have other antenna books in microwave region, most are all math, waveguides, feedhorns and so on. But a lot of it scales.

Irv

George

I'm not sure of the lengths of your "dipole" elements . I'm going to assume you have a 1/2 wave dipole antenna shortened to about 1/3 wavelength overall. That would have two identical elements about 1/6th wavelength each. If this understanding is correct, I could suggest a method of including 200 ohms in series with each 1/2 of the dipole.

A 1/6th wavelength long piece of 120 ohm coax would look like a 200 ohm inductor if it was shorted at its other end.
Perhaps I could describe a method of building an antenna by using two pieces of 100 ohm coax. It would look much the same as a conventional centerfed dipole but its total length would be shorter than the usual 1/2 wavelength. If you dont already have a picture of what I'd try to describe, maybe I can write more. But, I want to consider the outside of the coaxial stub to be the radiating surface.

Jerry

Hi George,

This was also an American specialty from the likes of Intel in the
late seventies. If there was any important feature deserving mention,
such was done "somewhere" - once.

The Kraus book you're probably referring to is, I believe, "Big Ear", which I don't have, but have heard about. Among his other books, Kraus' _Electromagnetics_ is one of my most-used texts on that subject.

For antenna books on specialized topics like log periodics, you might check Artech House.

For a loading coil of j200 ohms at 500 MHz you need an inductance of 0.057 uH.

Wind 4 complete turns of 16 awg wire on a former 5.6 mm diameter, 10 mm long. Q will be around 600.

For the above little calculation and many others use program SOLNOID3.
Download in a few seconds from website below and run immediately.

"Big Ear" is autobiographical with a good deal of discussion about the large antenna built near Delaware, Ohio. As I recall, there was a second edition too. Prof. Kraus gives credit to all who he worked with.

Smith published a big blue book on log periodic antennas. Most discussion is to be found in published papers. The book Cecil mentioned has a rehash of some of the conventional "wisdom" about LPDA. Use with care.

I find that the first edition (edited by Jasik) is the best of that series.

Watt has an excellent book on VLF (short) antennas.

I am still trying to find my own copy of LaPort's practical and insightful book. Please let me know if you find an extra copy. 73

I found the book, it is "Radio Astronomy" by John D Kraus, 2nd edition 1986
(first was 1966) printed by Cygnus-Quasar Books in Ohio. A lot of math.
Great book for EME building too

The power loss from the tuner is insignificant compared to the loss
from operating the coax at high SWR.

> I grounded out all devices in the shack but still
> receiving a lot of RF interferrence on tv, computer, and home alarm.
> Thanks for all the advice, really appreciate it.

Here's what's probably happening:

The antenna is not a good load for the coax on any ham band except 80
meters. The enormous mismatch where the coax joins the antenna, plus
the lack of a balance device, is probably causing the coax outer
shield to radiate. This permits your tuner to match it - sort of - and
at the same time dumps RF all over where you don't want it.

Since you don't want to fool with ladder/openline, the thing to do is
"fix the antenna" so that it presents a more-suitable load to coax on
bands other than 80.

Good luck!

662. moving two UHF TV antennas about the lawn till in phase

Newsgroup: rec.radio.amateur.antenna
Date: 2004-04-12 16:28:03 UTC
From: Dan Jacobson <jidanni@jidanni.org>
Message-ID: <87isg56u0c.fsf@jidanni.org>
Source record: 96813

Looking at these articles about stacking,
http://kyes.com/antenna/stackluge.html
http://www.signalengineering.com/ultimate/co_phasing.html
one worries about exact cable lengths to not get the antennas out of phase.

But say for a temporary set up, with two small UHF TV yagis, each on a pedestal that can be moved around the lawn, it seems one can cut the all three pieces of coax to any short length, and just move the antennas about, until one gets the best picture, meaning they are then also in phase, no?

Of course the driven element would be on the same side of each (but by using opposite sides, the second antenna could be pointed near directions we wanted to null out?)

I think I see where you're going with that, Jerry...that's pretty
cool. In fact, I can imagine making the center out of tubing and the
outer ends out of rod, and having it so the rod can be unscrewed or
otherwise unfastened and pulled out, making a very compact (narrow)
package for storage. Would have to be careful to make the rod
attachment a reliably low resistance so the Q of the effective
inductance would stay high. If the coax stub part is filled with
dielectric (like Teflon) it would give more flexibility about the
lengths and impedances.

Cheers,
Tom

Tom

I was actualy thinking about George's antenna with the coax's center conductor as being the little 'rod' and the outer jacket of the coax as the 'tube'. I was suggesting that the twin line feeding the pair of elements could be connected to the two 'rods'.
There would be alot of lattitude for changing this concept. Loading the coax with any dielectric could effect the mechanical rigidity and, of course, the electrical length inside the coax shorted stubs. You have some good ideas, already.

Jerry

This would probably be a violation of the electrical code, everywhere in the United States, due to the obvious safety issues. I'd really suggest against doing anything like this.

>Say, would water in long plastic pipes count as an antenna? I suppose
>it would have to be rather impure water.

Unless you're raising a crop of nori or other seaweed, and are piping around a mess of sea-water, I don't think the water in your pipes would have anywhere near a high enough conductivity to serve as a useful antenna.

>all three pieces of coax to any short length, and just move the
>antennas about, until one gets the best picture, meaning they are then
>also in phase, no?

I believe so. You'll find that there are numerous (in theory,
infinitely many) pairs of positions which will result in an in-phase
relationship. If you assume (without loss of generality) that the two
coaxes from the two antennas to the combining point are of equal
length, then placing the two antennas so that they are equidistant
from the desired transmitter will put them in-phase, and you can put
them anywhere along the equidistant line which is convenient. Putting
them too close together might result in interaction and pattern
disruptions.

Or, you can put one at a distance X from the desired transmitter, and
the other along a line which is (X + lambda) or (X + 2*lambda) or ...
away from the desired transmitter. This will also result in an
in-phase relationship.

If one coax is a bit shorter than the other, then the antenna with the
longer coax would go at distance X from the transmitter, and the other
at any position (X + delta + N*lambda) where "delta" is the
(electrical) difference in coax lengths and N is any integer.

>Of course the driven element would be on the same side of each (but by
>using opposite sides, the second antenna could be pointed near
>directions we wanted to null out?)

No, I don't think that would work well. That would result in the
second antenna having maximum signal pickup for the signals arriving
from the "null" direction. The antenna pointed towards the desired
source would have a much lower signal pickup from the "null"
direction, and even if the signals from the two antennas are out of
phase you'd find that their amplitudes don't match, and they would not
cancel out well.

A better approach is to aim both antennas at (or nearly at) the
desired transmitter. Put them in positions as indicated above, so
that the signals from the desired transmitter are in-phase. Then,

slide one of them sideways along the equidistant line. You should be able to find a position where the signals from the desired transmitter arrive at the combining point in-phase, but the signals from the undesired direction arrive at the combining point with equal intensity but at 180-degree phase difference, and null out.

Once again, there are numerous combinations of antenna position and coax length which can make this possible.

If you know the directions to the two transmitters/sources, and their frequencies, and the velocity figure of your coax, you can precalculate all of the lengths and positions and be very close to "spot on" when you set up your antennas.

There was a very good article on this topic (dealing specifically with FM radio broadcast reception) in Audio Magazine back in the first half of the 1970s.

Hi Dan,

As Dave says, "dangerous."

Instead, loop couple to the run and take what you can get.

>
>Say, would water in long plastic pipes count as an antenna? I suppose
>it would have to be rather impure water.

No. In spite of the supposed conductivity of salt water, it is not,
and fresh water even less (even if impure). You would do better
trying to load a coal seam.

Hi Guys,

If the goal is to reduce interference, aim the best null(s) at the
offending station and accept the combined mediocre peaks for the
favored station. The signal to interference ratio may be more
important than actual desired signal strength. Two antennas NOT
pointing directly at the favored station may combine enough signal to
allow optimizing the null. This probably has more combinations than
simple boresight aiming, and may yield non intuitive yet useful
results.

Forget about the feasibility of this question for the moment.
Could a column of mercury inside a tube of glass be used as an
antenna?
--

Yes, of course, but make mine copper, please.

Material Resistivity r(ohm m)

Silver 1.59
Copper 1.68
Aluminum 2.65
Tungsten 5.6
Iron 9.71
Platinum 10.6
Lead 22
Mercury 98

Incidentally, Keith Monk used to make a tone arm with mercury contacts.
(For those of you who don't recognize the term "tone arm" it was a device
used in the playing of "records".)

OK Cecil I'll bite. Yep! [I think there may be a Troll here :-)]

Mercury is a metal, albeit a dangerous one. It has a resistivity about 55 times that of copper. To a first approximation it's thermal coefficients are within a factor of 2 or less. It's location in the electrochemical series indicates that the relative potential between copper and mercury of -0.4546 volts would be subject to corrosive effects. Coupling RF to the column would require indirect coupling such as inductive.

Why in Heaven would you or anyone want to do it? [I think there may be a Troll here :-)]

Deacon Dave

Glass is an insulator and has dielectric properties.

My conclusion: Yep! But it would have much higher losses than copper

Sure, I don't see why not. You'd have to put up with a bit of tuning drift, as the resonant frequency would drop in hot weather or after you'd had your legal-maximum CW station running for a while :-)

There was a running gag over in rec.audio.high-end a few years ago, about the ultimate speaker cables: mercury-filled surgical rubber tubing.

Expensive, trouble-prone, toxic, and prone to cause unexpected visits from the hazmat team. Be the first on your block!

Think of how easily the antenna length could be adjusted.

An intriguing idea, but the health hazards of working with Hg would be
significant.

Also, overheating the mercury column would be really bad, and with the
higher resistivity, and difficulties in cooling the mercury, much more
likely.

Happy trails,

When I was a dumb kid in the 50s we used to go into the garbage of those hard of hearing and get their discarded hearing aid batteries to salvage the mercury. We got quite a bit and used it to make dimes real shiny and let the little balls roll around in our palms.. Several years ago I started to wonder what this might have done to me and I did some checking. Several dentists and a PhD metallurgist all said that the metal mercury is not toxic and is not absorbed but the salts of it are. In dental fillings it's amalgamated with silver. Just think how many kids played witth the stuff and how may dentists have handled and spilled it. When it is improperly disposed it can react with other chemicals and result in toxic compounds or salts and when these get into the water system fish apparently eat whatever feeds on the salts and concentrate it.
From the antenna standpoint I can envision a tall thin tube where mercury is pushed up to the right level for resonance but it looks like I squared R losses will be counterproductive.

yes, but how do you make a dipole? or a yagi?
Also if it wiggles, is that modulating the RF?
But wait there's more..... and you could make a parabolic dish out of it by spinning a pool of it at just the right RMP (some optical telescopes exist like this)
You could coat a copper wire with it to give it support (well.....)
And how can it be that hazardous? The dentist uses it in the fillings in our teeth, (that's close to home!)

No troll, just a wild hair. I got to thinking of using mercury as the conducting medium for an RF antenna switch and then wondered if mercury could replace the upper part of a whip where there is low current and high voltage. The mercury changing length in a thermometer triggered these unthinkable thoughts. Imagine changing the current through a resistor in order to tune an antenna by varying the mercury level.

Cecil,

No, it won't work.

Mercury, being a liquid at normal temperatures, is subject to hydrodynamic wave action. The RF couples into the hydrodynamic modes, and the resulting interference energy waves cause cancellation of the antiglare properties at the ends of the tube. The RF then leaks out and does not launch into the desired radio waves.

Of course the mercury has high local proton density, so it has been claimed that even small amounts of proton decay can negate the RF to hydrodynamic coupling, thereby allowing the essential glare properties to be maintained.

Cecil,

I asked this question about a year ago in some other group but the posting went unanswered. Here's (more or less) what happened about 4 years ago during a conversation I had with a fellow who emigrated from Russia many years ago. (It was a Sunday morning coffee shop ritual where my wife and I would walk to a nearby Starbucks and meet with a small group and discuss life, the universe, and everything as we overdosed on several venti lattes with two extra espresso shots...) He once mentioned a Russian text that detailed a mercury filled collinear antenna. It was not completely filled with HG but had electrodes at the ends that connected to cylinders of mercury. The article claimed wideband performance and low noise. I asked him to sketch out the illustration (bear in mind he's not a radio guy) and he sketched a collinear antenna.

```
|
|
|
|
---+-- feedpoints at +
[
---+--
|
|
|
|
```

This is the best (crude) ascii rendition of the sketch on the napkin, but you get the picture.
He described the ends were electrodes protruding into a cylinder of HG. I have yet to build the thing, but I do have a source of HG if I need it. he claimed the book was a KGB cold war technical manual (obviously written in russian) that he happened upon. I cannot testify to the authenticity of the article nor its origin, but I reiterate, he was not a radio literate fellow, but very well read in a broad field of mainly business, economic and political topics. When he sketched the illustration from memory, he even said "I'm not even sure it this is right, but this is how I remember it..." and yet the scribble was accurate.

I still intend to try it out, but as usual, procrastination rules!!!

Pat

Hi Henry,

You may as well had said several fools - especially the metallurgist
passing as a toxicologist. The Dental practice is one of the single
highest pollution hot spots of industry and acids in saliva are known
to leach Mercury.

There is NO MINIMUM EXPOSURE LEVEL to Mercury. No matter how little,
it has some debilitating effect that is measurable.

I did see a website about a person making an antenna out of the very substance. The link referes to a loop antenna now, but IIRC, this person made a antenna out of water in a PVc pipe. It was mounted on his Jeep. A 40 meter antenna, I believe. Strange, very strange

The page which gave the old link was on the A6CV site:

http://www.ac6v.com/antprojects.htm#W

and ther it is. Sorry I can't be more specific, I am dealing from memory, and was very amused at the time.

Had the same wild hair once.

One problem is that changing the length through temperature requires a
thin column of mercury in a stiff container; probably not ideal for
an antenna.

I came up with a bunch of other practical issues that I'm sure will all get
posted here in time.

The best use of mercury in antennas is to go down to the creek and
gather gold with it. Sell the gold and buy an antenna.

Hi Henry,

Another point of toxicity. Because the nuclear "Boomers" contained a
closed loop environmental system, ALL such batteries were banned from
the boat irrespective of their need in ANY equipment. We had to make
do with substitutes and jury rig our own holders or means to provide a
voltage for key equipment that would work fine on surface craft.

Utter nonsense.

Ever hear "The poison is in the dose"?

There is some amount of every element in your body, including mercury,
plutonium, arsenic and anything else you care to name.

The key here is "closed environment", which means crap accumulates.

A lot of things are banned on subs because it is easier to ban them than
it is to monitor them for for safe levels and then clean the whole damn
sub when a level gets too high.

None of this means you should get your panties in a wad because there is
a mercury wetted relay in the house.

Well, dooh...

So are you saying there are no restrictions on ANY materials used in or
brought aboard a sub other than those containing mercury?

You said:

"There is NO MINIMUM EXPOSURE LEVEL to Mercury. No matter how little,
it has some debilitating effect that is measurable."

What is the "debilitating effect that is measurable" of exposure to 1 atom
of mercury? How about 2 atoms of mercury? Three?

According to the the ATSDR:

"The EPA has set a limit of 2 parts of mercury per billion parts of drinking
water (2 ppb).

The Food and Drug Administration (FDA) has set a maximum permissible level
of 1 part of methylmercury in a million parts of seafood (1 ppm).

The Occupational Safety and Health Administration (OSHA) has set limits of
0.1 milligram of organic mercury per cubic meter of workplace air (0.1 mg/m?)
and 0.05 mg/m? of metallic mercury vapor for 8-hour shifts and 40-hour work
weeks."

Looks to me like there are at least three entities other than Battelle
Centers for Public Health Research & Evaluation that found minimum levels.

>Mnay thanks, John G0WPA

I have one, and you need to get the aux antenna as close to the source
of the noise as you can. I could never really get good results, because
I was using a 4 element quad at 120 feet and it could hear noise sources
a long way from my QTH. My aux antenna couldn't, and there wasn't
enough adjustment in the gain control.

When I was a kid, my denist used to squeeze the mercury out of the
fillings with a cloth, and just let the liquid mercury fall all over
everything. He said it had been "passivated" or something like that
and thus rendered inert and harmless.

Do you limit your glass of water to 2 billion atoms of H2O? Asking
about atoms in the face of living a real life is absurd and mocks the
real dangers.

The EPA has also allowed for risks that endanger life in Asbestos. It
is a ongoing tragedy in Idaho currently. Ask them if they believe in
the current administration's track record. Using watered down,
industry leveraged numbers to cross-correlate to safety is fine if you
want to die your life that way.

However, back to Mercury. The current science eclipses all these
"standards" you quote. It is a matter of degree. The standards offer
that your IQ may slip 10 points at their levels - the question is do
you shrug off better practices that merely reduce it 5 points, or is
below the "standard" threshold suddenly no loss whatever? Clue: it is
a continuum, there is no safe level of exposure. If you feel fine
shaving half a point, sobeit. If it amounts to 0.05 point, bake a

cake and have a party. Offer guarantees of no loss whatever below current "standards" and you will buy the farm in liability.

Marcello,

all those CB antennas are JUNK. Their advertisement are non-technical
promises for people that don't understand HF-Radios at all.

3MHZ bandwith SWR < 1.2:1 and 5000 Watts are simply LIES!

In practice - an vertical antenna without counterpoise or grounding
will not work. So the result really depends WHERE you mount it and HOW
you mount it and HOW you GROUND it.

Take a 7,2 long rod and try to find out with MMANA what's about it.
You will be surprised. Maybe they have a L/C at the feedpoint to
compensate the SWR at the center of the CB frequencies.

SNIP

As an Aerospace Design Engineer [1964 - 1986] and Major Military Systems Chief Engineer [1986 - 1992], MERCURY was/is a prohibited material in design. Any 'only solution' conditions had to be explicitly approved by higher authority than the PCO [Program Contracting Officer]. This generally was understood as SPO [Systems Program Officer ... Rank 2 stars or higher].

Dale,

If you do not intend to perform front-to-back tuning, then the rule of thumb is to cut the reflector for a frequency that is 3% lower than the driven element design frequency.

For example: if your design frequency is 14.150, you divide by 995.2 for the driven element length of 70.3 feet. Then subtract 3% for a reflector frequency of 13.726 / 995.2 = length of 72.5.

Yes, it works as described. I built a 20M version and have it mounted
at about 45 ft between two trees. I'm working anything I can hear
with 135 watts...it takes a few calls sometimes.

I use it with a tuner on 40 thru 10 with very good results. I highly
recommend it.

No assumption here. I agree that this would be VERY difficult, although the
"upper part" sounds feasable. Just replace the screwdriver motor &
mechanism with a pump...

Hi Toni,

Good references. The products they would sell would be very useful as some problems fail other resolutions (Gerhard was lucky). Myself, I have a Mains isolation transformer for my floating battery charger (and batteries) which powers my equipment. For me, Ground is at the Antenna connector output (actually a threaded stub nearby) and not both there and through the third wire. I also have isolation transformers for the audio signal that goes off to my 'puter.

A Scanning Electron Microscope to eliminate QRM ???

Seriously, this must be something like the MFJ 1026, no?

I suspect it is.
With the common canceller:
The thing to keep in mind is that what you are doing is creating a null in the antenna pattern. Therefore, your "sense" antenna must pick up enough of the unwanted signal to do this given the gain and noise limitations of the box. Also, one null is a minimum. There could be more since you have an indeterminate phased array. Also, if you are trying to receive from the same direction as the unwanted signal, you could have trouble as well.

>
> George K6GW

Keep in mind, George, that it is generally the PHYSICAL antenna that creates the pattern, so there can be degradation in directivity with shortened elements. Depends on just what you are doing.
For a small Yagi, a 1 dB reduction in gain can mean considerable widening of the lobe. If you are depending on a narrow lobe, this may reduce the effectiveness. I carry a three element tape measure beam in my trunk. It has a pretty wide main lobe as it is, but a null to the rear for directivity... but I have a substantial 8" cardboard tube, mounted so I slip it in and out easily... makes deployment a snap. Just watch the wind direction.

P.S. I don't use any hose clamps..cheaper that way.

The two antennas behave as one, a director with a reflector, with a null in the radiation pattern. Varying the phase and magnitude controls have the effect of rotating the antenna pattern and varying the spacing between the two elements.

Orientate the noise antenna in a different direction to the main antenna and if you know where the noise source is located then maximise noise pickup from the noise source. There will be one null only if there is one noise source. And usually you can consider yourself lucky if you can find it.

Another tactic is to arrange for the noise antenna to pick up a minimum of the wanted signal if you know from where it is coming. If the main antenna is outdoors and high in the sky and the noise source is very local, ie., you are in the noise near-field, then install the noise antenna indoors at ground level.

A null is impossible if signal and noise arrive from exactly the same direction. If from nearly the same direction then the wanted signal will decrease almost as much as the noise. But the situation can usually be improved yet again by changing orientations of one or both antennas.

If the main antenna picks up stronger noise than the noise antenna then a null can be obtained only by increasing gain in the noise receiver.

Its all a matter of phase and magnitude.

Hi John,

I live on a small city lot and my main problem is the ever
increasing level of local QRM and the number of QRM
sources. The limited space for antennas makes is difficult
to find a way reducing this local QRM. Large directional
antennas are not possible.

My current project is summarised on:
http://home.plex.nl/~jmsi
It uses two active broadband small magnetic Alford loops.
Both loops can be rotated.
Addressed are distance to qrm sources, antenna balancing,
nulling, noise cancelling, diversity reception and directivity
using both loops in an array.
At the moment I still use the MFJ-1025 noise canceller.

May be it helps you reducing the QRM.

Hmmm, number 2 element shouldn't be in anyone's body. It is an artificially produced element, and if it does enter the body, it's characteristics make the consequences are particularly nasty. And it doesn't take much at all to produce that nastiness.

Good one, JJ! 8^)

Mercury isn't very harmful by that route of exposure. You could polish quite a few dimes if you like, and not suffer much if any damage through skin absorption.

But!

Inhaling the fumes is another thing entirely. Mercurey poisoning has been known about for a long time now. Daggureotypists in the early 1800's often suffered from mercury poisoning as they purposely fumed the image plates to develop the images, producing a silver amalgam on the surface in accordance with how much it had been exposed to light. A beautiful but deadly process.

The feltmaking process used to use mercury as a preservative, and the saying "mad as a hatter" was coined for a reason.

And yet we still have people today that think that caution in handling mercury is some kind of "liberal" plot or something.

730. Help Getting a PK-232 to Key a TS-570 in CW

Newsgroup: rec.radio.amateur.antenna
Date: 2004-04-13 20:27:32 UTC
From: "Dick, AA5VU" <aa5vuNOSPAM@arrl.net>
Message-ID: <aa5vuNOSPAM-1DB0ED.15273113042004@newssvr22-ext.news.prodigy.com>
Source record: 96681

Yes, I know this is an antenna newsgroup but the people who read this traffic may be able to help me.

I have always used the PK-232 for RTTY and Packet and never really messed with the putting it into the keyboard mode for CW transmission. For grins I decided to try this morning and ran into all kinds of problems and could use some help.

First the TS-570 was designed for the operator to use his personal keyer with the 570's internal keyer. The internal keyer is activated by plugging in a Stereo Phone plug. If you want to use and external keyer (like a PK-232), you have to use a Mono (tip and Sleeve) Phone plug.

The PK-232 has a Plus (+) and Minus (-) RCA jacks on the rear. I cannot find anything at Radio Shack that goes from two RCA's to one Mono Phone. Really weird setup. I found a RCA to Mono Phone plug and and it causes the 570 to send a stream of dits when plugged into the (+) output on the PK-232. If I plug the same cable into the (-) RCA jack on the PK-232, it causes the 570 to send a stream of dah's.

Looks like I may have to rig up some special non standard cable taking the center of the (+) RCA plug to the Tip of the Phone Plug and the center of the other (-) RCA jack to the sleeve of the Phone Plug and let the grounds float.

Do I had to dummy down the TS-570 buy turning some menu functions off?

Anybody out their CW keying a TS-570 with a PK-232?

Dick, AA5VU

ps: Just made up the cable mentioned above and when I turn on the power, the TS-570 starts sending a constant string of dit to the side tone oscillator... like someone duck taped a Bencher.

I must be doing something pretty dumb. Page 3-6 Section 3.3.5 of the PK-232 manual is really confusing with a totally useless Direct CW Keying Cable diagram.

Again, anybody been able to key the TS-570D(G) using a PK-232. I need help.

Dick, AA5VU

Over time, it is a self-correcting problem.

Holding it in your hands is more of an issue if
A) you have some sort of wound, and some could contact your
bloodstream, or more likely
B) if you do not _thoroughly_ clean it off your hands before touching
food, rubbing your eyes, smoking a ciggie, etc.

>None of this means you should get your panties in a wad because there is
>a mercury wetted relay in the house.

In the mid 80s I was involved in the start up of a 100KW photovoltaic demonstration project. I worked for an electric utility, and they wanted to show how great amorphous silicon solar cells were, so they could manufacture and sell them.
The PV array was capable of 300VDC at around 350 amps at high noon on the 4th of July in the deep south. The array fed 4 25KW inverters which converted all that DC into 480 VAC 60HZ which was put on the power grid.
The interrupters, or circuit breakers to the inverters were Mercury wetted contactors. The guy that designed the inverters used the AC interrupting rating of the contactors. The PV array was capable of more than double the DC interrupting rating of the contactors resulting in 4 exploded Mercury wetted contactors. The inverters had problems which resulted in full load rejection during start up.
Well, the exploded contactors produced an abundance of mercury vapor as well as little blobs of the stuff all over the floor in the inverter building. This just about closed down the whole 1.4 million project, because a lot of folks got their panties in a wad. As for me, I went around sucking it up with a suction tube, putting it in a bottle for future use in antenna projects.

How come no one told me what an SEM is??

> There will be one null only if there is one noise
> source.

Reg explains well, but I don't believe this item is, in general, true.
One example case could be two identical verticals where you wind up with
them fed 180 degrees out from each other. There will be two nulls broadside
to the antenna and 180 out, in direction, from each other (an Adcock).
Change the phase and both nulls tilt toward the direction of one antenna or
the other...untill they coencide and you have the cardioid.
With at least one directional antenna, the "other null" may be where
there is little pickup from the directional antenna and therefore non equal
signals and the "noise sense" antenna signal would dominate, in essence
hurting the directivity of the "main" antenna. (Because there isn't enough
from the main antenna to cancel what comes from the noise antenna.) Ya
gotta have both to cancel.
Therefore, it's a bit more complex as well, but killing the noise may
far outweigh other problems. But as Reg says, you want to maximize the
niose pickup in the noise antenna and minimize the desired signal in the
noise antenna.

Automatic systems like this are used on "radio gun ships" Lotsa radios
trying to interfere with each other. Sample the offending transmitter at
its output and cancel it at the problem receiver.

Mercury can be forced through a solid plate of steel. Such is its
ability to migrate through barriers.

>B) if you do not _thoroughly_ clean it off your hands before touching
>food, rubbing your eyes, smoking a ciggie, etc.

Hi Gary,

I just attended a Nanotech seminar presentation 4 hours ago on "The
Collapse of Langmuir Monolayers" that showed the human body has
roughly 2Mï¿½ of skin surface area, OR 100Mï¿½ of Lung surface area, OR
300Mï¿½ of Gastro Intestinal surface area. The later two have a
monomolecular air/water interface - the Langmuir layer.

The decay products of nuclear breakdown (the electron emission) is no
hazard due to its inability to puncture the dermal layer - inside the
body it leads to chromosomal breakdowns that gives rise to cancerous
growths. Same vector, two different paths separated by lack of
caution in the errant belief about exposure levels leads to grief.
[Another lesson learned in close proximity to the Boomers, and 24
Nuclear warheads stored within 10 feet of my workbench aboard ship.]

I am considering trying to make a feed point balun at the center insulator,
but I won't have much room. I've got it laid out horizontally and it tunes
up pretty good as is, but I have not gotten with the guy to make my little
center insulator.

I'm mounting this above my 6m quad as an omni-vertical... I figure I can
stick it on top of a PVC pipe and it will interfere less with the quad than
a 1/4 ground plane would (and it looks better).

Thanks for the responses... I don't think heating the whip will be a
problem, though loss might... I'm only running 5 watts key down.

I'm really shooting for the occasional cross polarized weak signal
contact... though I think that the difference in gain between the dipole and
the (horizontal polarized) quad will end up meaning that vertical signals
are about the same... but it's worth a shot.

Hi Jack,

They were ALL my Boomers (COMSUBLANT Charleston). USS Holland AS-32
Fleet Electronics Calibration Laboratory (Repair Services division).

Battery holders for test equipment that took only one particular
shaped coin cell (the mercury cells in commercial gear). They were
usually bias voltages for specialized test equipment (maybe torpedo
sonar test sets, but recollection is hazy in the particulars; coulda
been crypto gear with RAM). I am well aware that mods were frowned
on, but our shop had special dispensations from the Pope. No one
argued authority with us who wanted to ship out (and we did get our
quota of those who "just had to" lose a fight).

I do know it wasn't for the nuclear pile sensor. They hauled me outa
the rack at midnight to take over measuring at least 10 GigOhms
because all they could muster up was a reading of 20X10^9 Ohms. I was
puzzled why they needed less and they explained "their" dictionary
described Billion as a million, million. I told them that was the
british Billion but only after proving it to their Captain - the sub
wasn't going to cast off without that check item and there was a lot
of brass looking over our shoulders as I balanced the bridge. As it
was in the common passage way to Sherwood Forest, someone invariable
had to clamber past and would peg the meter for a minute or two.
After about an hour I got back to my rack. I really did like the
Diesel Boats better.

Isolating the equipment from normal power ground and establishing a new common ground point was a common practice in the computer industry some years ago. The high end stuff had triple shielded iso-transformers. The first shield was connected to the AC neutral. A sort-of ground, but probably useful in allowing shield capacitive current to be returned to the neutral and avoid tripping GFI protected circuits. The second shield was connected to building power ground (the "green wire") and only needed to deal with potentials between neutral and ground, hopefully fairly low The third shield was the "isolated ground" common point, connected to the equipment ground, secondary neutral, and a local "earth" ground (building steel, etc.)

Richard,

The Tender crews in Scotland hated all submariners, no exceptions. We thought they especially hated us but I think it was universal. Maybe because when it was time to get underway we used questionable tactics to separate the materials we needed from the Tender's inventory w/o always using the proper channels, shall we say. If they could've put mercury in our coffee they would've.

Umm, no, most people today think standing over a vat of heated murcury or
chewing on something impregnated with mercury is not a very good idea.

That doesn't mean you ignore the hazards or go screaming in terror just
because you see mercury.

Any reason not to feed each wire through the wall using those old time ceramic insulators with the hole down the middle, you know, those 4 or 5" long while tubes that were used in the knob&tube era of electrical wiring. Since I would be making my own feed line here, I could rejoing the pair on the other side of the wall and continue with my spacers until I reached the ceiling, and then to the process again, eg. putting each wire thru its own tube and then continuing with the spacers on the other side.

It is either this or using that idea of double coax feed with the coax grounds connected to each other at one end and grounded to the tuner (?), anyone have sucess with this method of coming into the shack via balanced lines?

If one is constructing ladder line, is the point to design the ladder line so its impedance matches the characteristic impedance of the antenna itself at its feed point?

The theoretical feed point impedance for a full wave loop antenna is approximately 100 ohms, (but this does change, and is dependent upon antenna height above ground, near-by structures, and ground conductivity.) Should I try to make my ladder line to get as close as possible to this 100 ohm? In other words, does it make any difference reallly if my (12 guage insulated) ladder line uses 4" spacers (550 ohm) or 2" spacers (468 ohm) or 1" spacers (385 ohm) in the final analysis? Should I just go with the 4" spacing because it looks cool?

Anyone think that maybe non-insulated would be a better way to go?

Zeno

751. Using a metal roof as a ground plane

Newsgroup: rec.radio.amateur.antenna
Date: 2004-04-14 07:24:35 UTC
From: Rick Frazier <rick@rickfrazier.com>
Message-ID: <407CE747.6B6E5531@rickfrazier.com>
Source record: 96702

Hello:

I've just received a 5BTV, 5 band trap vertical (75-10M), and as with most of them, I would suppose the instructions suggest that ground mounted is ok, but elevated it would be better to use radials.

I am planning on mounting it on the peak, near the center of a rather large metal roof. The roof is approximately 58x38 feet and has a pitch of 4" per foot down from the peak. The roof is composed of 39" strips of metal roofing, and isn't quite solid metal, but has three sections three feet wide that use fiberglas panels for the top 35 feet of each section on each side. (These perform the function of skylights). The only "bonding" of the roof panels to one another are the stainless steel screws that hold the panels to the roof substructure, which are placed about every two feet along each edge, and in three or four places at the top of each strip of metal roofing where they connect to the ridge. Each run (except for the fiberglas panels) is a single section approximately 3ft wide and 19+ feet long. There is a connector panel about 3 feet long at the bottom of each of the fiberglass strips, so the bottom edge of the roof is continuous along the 58 foot length. (Think of it as a nearly solid roof with three strips missing on each side, making a 3 foot by 16 foot slot in each of the three skylight locations on each half of the roof.)

After this description, if you're not completely confused, what I'm wondering is whether the roof will provide a decent ground plane for the vertical antenna, or whether I should add specific ground radials....

Of course, I'll have to figure out a decent mount so it actually stays on the roof with our winds (which are typically not that bad, even here in Hawaii where I live.) It's a rare occurrence when we have 50mph winds, but 20-30mph "trades" are more normal.

Anything I should be looking out for?

Thanks
--Rick

an impeadance transformer at the end of a 1/2 wave of wire actually does
work. The transformer though needs to be of specified values for L and C
to properly match the line to the 1/2 wave radiator. I should know, I have
built more than one using the Radio Amateurs handbook and the ARRL antenna
compendium for references.

well, thats probably for grounding (thats about all I use a copper rod
for). However, the shortest low impeadance path to that rod is the key
(again, there are references to it in the Amateur radio handbook).

Hi Rick
One advantage of a vertical on a peaked metal roof as opposed to one on a

flat ground plane is that the feed point impedance at resonance is very close to 50 ohms, depending on the pitch of the roof..
I have a Fluidmotion BiggIR vertical on the peak of a 3500 square foot aluminum roof and I must say it's the best vertical installation I've ever used.
Some scheme to limit common mode current on the feed line is in order; In my case I just looped the coax and control cable seven turns. Other schemes work too.

How close are you to the water? Or are you up high?
You didn't say if you're in the Hawaiian islands generally or on the Big Island.
The reason I asked is that I once (1970) operated from St Johns in the Virgin islands. Some of the operation was from a habitat under water (Tektite II). We used a HiGain 14AVQ trap vertical on a barge above the habitat with a big piece of cable splayed out in the salt water. That antenna worked quite well as I recall.

> damage something.

Jim,

Thank you for taking the time to respond. I read and referred to both manuals before posting the request for help. Ny first reaction to your message was to be pissed at someone telling me to RTFM. Guess what? You were right!!!

The problem has been found and fixed. I misunderstood the manual and was using a Mono Phone plug in the "PADDLE" jack. On second reading (at your suggestion) I noted the "KEY" jack uses a 3.5 mm (1/8") Mono plug.

Like I said in the posting "... I must be doing something pretty dumb." Everything is now working absolutely perfect and I am a little red-faced.

Thank you for the help!

Thanks to all, I know that marketing write sometimes false advertisement.
It was only to compare my vertical 5/8 ground plane antenna, with 8
alluminum radials at 90° degree, with the I-max 2000 antenna that in Iternet
it is know like "miraculous antenna" for the 11 meter band.
Here in Italy this antenna is not to be found, than I can't do the
simulation, becouse I don't know the fisical carateristics.
Thanks for the answers, excuse my grammar or my syntax errors.

The parallel coil at the base, active on the lower bands to raise
the feedpoint resistance, provides a DC short automatically.

> If one is constructing ladder line, is the point to design the ladder line
> so its impedance matches the characteristic impedance of the antenna
> itself at its feed point?

The point of using ladder-line is so the antenna impedance doesn't
matter (within reason). SWRs on the ladder-line range up to 30+:1
with small ill effects. A 30:1 SWR on ordinary coax is a signal
killer.

Consider that the feedpoint impedance of an all-HF-band antenna
might range from 60 ohms to 3000+/-j3000 to 6000 ohms. The SWR on
Z0=600 ohm line would be around 10:1. The SWR on Z0=50 ohms would
range up to 100+:1.

> The theoretical feed point impedance for a full wave loop antenna is
> approximately 100 ohms, (but this does change, and is dependent upon
> antenna height above ground, near-by structures, and ground conductivity.)
> Should I try to make my ladder line to get as close as possible to this
> 100 ohm?

Nope, go for simplicity. There's not much practical difference between
Z0=400 ohms and Z0=600 ohms. And you may be able to use the impedance
transforming properties (on a line with reflections) to your advantage.

> Anyone think that maybe non-insulated would be a better way to go?

Non-insulated wire allows one to hang parallel stubs up and down the
line, useful for matching purposes. It also allows one to measure
actual feedline voltages.

Yes, it should, even with the fact that it is not continuous sheet metal
it will probably still have a LOT more surface area than a few radials.
I would ground the vertical well to the roof, test the sheet panels are
electrically connected and go for it. If the antenna doesn't seem to
perform well you can always add radials later. I used a metal roof once
with a vertical and it worked very well indeed.

>Should I just go with the 4" spacing because it looks cool?

Fer Sure, Dude!

The choice is simply one of maximizing copper to minimize loss. If you expect a wide variation of Z through using the radiator across a larger variation of frequency, it is hard to choose one single determiner of line Z outside of this consideration. You could use the same logic to select 50 Ohm line (there is absolutely nothing magical about the value); however, cost becomes prohibitive due to a larger conductor for the inside lead driving the size of everything else to obtain the same loss figure as the cheaper, simple twin lead construction.

So, there you have it, cool and cheap (true to only the frugal Amateurs's perception of reality).

As for another question about coming in through the wall. You idea would work suitably. The only problem is in having it penetrate house insulation that is foil-backed (without you being aware of that being so). Some would offer the penetration presents no problem as it is for a very small interval. In the large scheme of things, quite true; and yet as a site dislocality (humorously called a bump in Z) this is where additional SWR will be present with a corresponding magnification of V and the possibility of breakdown. This is unlikely, but this would be where it happens if "likely" occurs. As things go, it is all a probabilistic issue - the insurers have tables for this.

1/4" / 6 mm PTFE rod. From Radiospares in the U.K.
but there must be suppliers in the States. Cut into
suitable lengths with a hobby knife - I used 125 mm
but not critical. Drill holes 5 mm from each end,
making sure they are parallel. Holes should be about
1/2 mm smaller than the wire you are going to use. I
used 19/0.2 silver plated copper with a PTFE jacket.

PTFE is fairly soft and easy to work with hand tools.
The stuff available here is white and surprisingly
very unobtrusive visually, certainly a lot better
than black windowed 450 ohm twin.

Slit from the holes to the ends of the rod with a
hobby knife. Ease open with finger and push the wire
in. I used an aluminium ruler to push with. It will
'click' into place. You can adjust the spacer positions
easily but the grip is enough, even with PTFE, to keep
the spacers in place. Space the rods 12" to 18".
This will also work FB with bare copper conductors.

Apart from its excellent electrical characteristics
the PTFE is very good at shedding rainwater, which
can be a problem if you use other plastics, especially
tubes.

You now have some very posh mil-spec ladder line. I
can easily make 30' an hour with hand tools.

Since there 59 of the elements measurable with current (as of 1998)
technology, I think this would be a pretty sure bet.

See http://web2.iadfw.net/uthman/elements_of_body.html for a pretty good
list.

Rick,
It ought to 'work fine 'n last a long time'! Well,
maybe not a real long time, but a couple of years or
so (don't tempt Moma Nature LOL).
Your metal roof should make as good a ground as any
dirt/radial system, especially where you live, with the
volcanic 'stuff'. Just how 'good' will depend on the
mounting location, the pitch of the roof, and so on.
There's no way of predicting exactly what your results
will be as far as the input impedance since it will
depend a lot on how well you tune the antenna.
'Doc

PS - If it doesn't work well, send me a bus ticket and
I'll help you 'fix' it???

Hi Rick,

I live far out in the alaskan bush, and use a very similar antenna system. I have a 5BTV mounted at the center of my peak ridge, and grounded to the Galvinized sheet Metal Roofing. The only thing I did different than you have suggested, is to run a Cooper Braid along the ridgecap that connected to each of the sheets of Roofing. This vertical Antenna System loads really well, and has provided good serviceablity for me.

Tnx to both Richard and Cecil et al, I think I am good to go. I will most likely use the uninsulated wire for the diy ladder line. Although I do not quite understand the thing about stubs and am not sure how I would be able to measure anything along the ladder line since it is actually high up in the air for the most part (I might be able to measure something at its ends tho....what exactly does one need to be measuring up there?). Sorry to be so Elmer-needy....

I just happen to have a bunch of that black poly 1/2" irrigation tubing, which cuts up easily, and is apparently a good choice for diy ladder line because of its UV tolerance.

There is no foil-backed insulation to worry about coming into the house peak or ceiling. I have a bucket of those old porcelin knob&tube feed thru dealies out in the barn.

I am making some masts out of whatever I can recycle, mostly old metal tv telescoping masts. I will have to guy them if I get them up as high as I possibly can for the four corners of the loop. I was thinking of using pulleys and dacron for the guys, pulleys so I can redo the guys after years...and they look like they are about to fall apart etc. without having to take down the poles.....or should I use wire for guys? The masts are metal anyway, maybe wire guys are ok, what do you think?

-Zeno (although I probably will be "Bill" when I finally get on the air again)

They just gave me KG6UHM, but I think I either want my old expired call back or concoct something new....with good cw rhythm....and "phonetics" which reads like a novel......

Hmm, Ok then maybe i'm not asking the correct question. I was thinking if there is a way to make a screwdriver antenna appear or act like a "loop" style antenna in which the radiator is connected to ground creating a "dc short"

At my previous residense I had a large loop antenna and i was always impressed with how low of noise level it had in comparison to other antennas.

Hi Bill,

Black is usually indicative of carbon content; but I wouldn't let that stop me the first time around if it was handy (pop it into the microwave and nuke it to see if it gets hot - this is not about microwave frequencies, merely tendency to conduct and to dissipate).

Dacron, I think, is the more long-lived, goferit. Use wire, don't use wire; it won't matter much.

As for measuring stubs. Not sure how that appeared as a concern, but as to measuring in general, attach a known mismatch at the far end and measure the SWR across frequency. If the readings look better than you would have reckoned, then you have something wrong along the way (loss tends to sweeten the appearance of problems). The known mismatch could be as simple as a direct short at even multiple of quarterwaves away (or open on odds - whichever). Make sure to account for velocity factor, or simply compare the physical length to the measured electrical length of the short/open. This, too, will give you an indication of line health. You can go farther and calculate the actual line Z, but who cares? Only guys like me (and that hardly counts for much).

Hi Jeremy,

A large loop? From the radiator out and back to the ground mount?
Most short loops need capacitance (kinda the inverse of short
monopoles need inductance - hence the utility of screwdrivers). For a
larger loop, you may need additional components (dare I suggest
capacitors again?); but if you didn't give it a try, then you might
lose your amateur status; any way, you can attach a cap anywhere for
a quick-see.

Assuming the screwdriver antenna is mobile, a full-wave loop
is hard to come by. I have heard of such being attempted using
gigantic capacity hats but I haven't seen any in action.

Zeno,
"Swarming" means that because of the 'memory' of the wire
used to make the 'twin lead', when it's turned loose from
whatever you fixed it to to build it, it tries to assume it's
former shape. Usually results in a 'rat's nest' of wire in
a not so compact ball, LOL! Not really something to waste a
lot of worry on, just be aware that it can happen.

Zeno,
No reason why it wouldn't work, just use the normal care
in selecting a 'spot' in the wall that doesn't hold any
other wiring, etc. Using feed-throughs like that is sort of
'permanent', can't remove it without repairing the holes.
The board in the window thingy isn't 'permanent', just take
it out of the window and replace the screen (if any). The
choice is your's and your 'significant other's (probably more
her's, than your's, right?)...

Tying the ladder-line to the trailer hitch of my GMC pickup and
stretching it a bit solved all those problems.

Perhaps the term 'Sproinging' might be better. You take it out in a
neat roll, let go, it goes 'Sproing!' and you have a rats nest. When
you get ready to put it up, call a couple of chums over for an
antenna raising party and let them loose the coil -- then let them clean
up the ball of wire! :-)

As others have mentioned, check the continuity
between the panels... some metal roofing comes
coated with plastic or paint (even if it looks galvanized).

If the skylights you mentioned interfere with
the ground connection along the peak of the
roof, I'd go ahead and run a strap down the
center of the roof peak line, bonding it to all
metal panels along the way.

Metal roofs can help, or hurt! If the connections
are bad between panels then you'll get loss and
noise. Otherwise, it's the best of both worlds, a
long-lasting roof that makes an excellent ground
plane.

Markland Awarded Patent for New Gas Plasma Antenna Technology Designed for Homeland Security and Military Applications
Wednesday April 14, 7:00 am ET

Plasma Antenna has potential to Revolutionalize Antenna Technology

RIDGEFIELD, Conn.--(BUSINESS WIRE)--April 14, 2004-- Markland Technologies, Inc. (OTCBB: MRKL- http://www.marklandtech.com), an integrated homeland security company, announced today that its gas plasma research team has been awarded US patent # 6,710,746 for a gas plasma antenna element demonstrating re-configurable length. A gas-plasma antenna could revolutionize antenna technology due to its unique benefits over traditional antennas. A plasma antenna operates with greater stealth, has the ability to dynamically transmit/receive multiple frequencies, and is extremely portable.

The company intends to direct its research toward applications for Military and Homeland Security. This includes applications such as secure broadband wireless communications and stealth radar. The development of this technology has been funded to date through Small Business Innovative Research grants from the US Navy and Army.

The US patent awarded to Markland relates to plasma antennas having re-configurable length, beamwidth, and bandwidth. Traditionally, antennas have been defined as metallic devices for radiating or receiving radio waves, or as a conducting wire, which is sized to emit radiation at one or more selected frequencies. As a result, the paradigm for antenna design has heretofore been focused on antenna geometry and physical dimensions. Markland's innovative gas plasma antenna patent portfolio changes the paradigm, as it is now possible to design antennas which have greater flexibility and security than conventional antennas.

Markland CEO Robert Tarini stated, "We anticipate that our Gas Plasma Antenna (GPA) intellectual property portfolio will provide a revolutionary new set of advanced capabilities to the Department of Defense and Department of Homeland Security as they endeavor to deal with an ever changing landscape of challenges. Our plan for the GPA technology is to transition it from its present stage of development, where we have multiple active government funded contracts for advanced research programs, to the next stage, where we hope to be awarded product development contracts to commercialize the technology."

791. Element Design with Loading Coils

Newsgroup: rec.radio.amateur.antenna
Date: 2004-04-15 05:53:49 UTC
From: George <look@signature_to.reply>
Message-ID: <Nrpfc.11267$A_4.9729@newsread1.news.pas.earthlink.net>
Source record: 96642

I have a question that's probably easy for anyone with practical experience building UHF antennas. I need to make a shortened dipole (from tubing) at 450 MHz without sacrificing too much gain compared to full-size.

I have a design based on EZNEC. Total shortened "half-wave" dipole length is 0.32 lambda. Half of that of course is in each of the two elements. There is a loading coil in the middle of each element. EZNEC assumes zero length, non-radiating coils. In reality, the coil length is significant compared to the element length.

So, how do I build this thing considering the real coil length? Can the coil be inserted in the middle of each element without reducing the element length by the length of the coil? In other words, would final element length be 0.32 lambda plus coil length? Or, should the elements be shortened to maintain overall 0.32 lambda end-to-end length?

Thanks.

George K6GW

792. Antenna too long??

Newsgroup: rec.radio.amateur.antenna

I am trying to put up a dipole for 40 m. The formula calls for about 65 feet.

Between my tress I easily have space for twice that.

That would still resonate, would it not.

Tell me that longer is better, at least when it comes in multiples.

66 feet 4 inches drops you in the middle of 40 metre band.

33 feet 2 inch a leg.

Between trees is better than through them.
Re check everything, when the leaves are on the trees.

QRP HomeBuilder web site is at

http://qrp.pops.net/qrp/default.htm

They have dipole antenna software for free.

Best of luck

Uwe,
'Bigger/longer' isn't necessarily 'better'! A longer
dipole -may- resonante on the desired frequency, but the
65 feet (approximate) is really all you need. Twice that
length would probably work for you, but feeding it in the
center would also be a very bad impedance match for 50 ohm
coax. Not to mention will produce a radiation pattern
different from what you might expect. A full wave, instead
of a 1/2 wave, dipole can be made to work, but all things
considered, why bother?

Joe Cro N3IBX says his "big antenna" is resonant from 1500 kHz to 46 mHz.

It is a military inverted-V, 110 ft. long total, with each end terminated in a 150 ohm resistor driven into the ground, center fed through a 9:1 balun.

Assuming this is not an April 1 joke:

(1) What are the drawbacks to this antenna?

(2) What is the feedline?

(3) Is there any more information about this type of antenna?

(4) What is the point of burying the resistor, rather than one lead?

George. You can describe your loading coils to Nec by taking the
physical length of the coil, say, 1", and creating a number of wires
that divide into 1", say 5.
THen put a load on all 5 wires, the total load amount would be the sum
of the 5 loads.

This technique is used in one of my sample antenna files,
'mobile.ant' at:
www.nec2go.com

I haven't read the article, but I expect the word 'resonant' is
incorrectly used.

Any antenna terminated with real resistors into the ground is generally
a traveling wave non resonant antenna.

In addition to radiating some of the RF it also wastes some of the RF in
the two load resistors.

It should work but not as well as a 110 foot inverted vee, open wire
feeders and a tuner.

Welcome to real world. If you want to read more about the loading coil controversy, go to my web page www.K3BU.us and snoop around ARTICLES, you will get the picture. Eznec doesn't understand real coils, you can try to substitute the coil with hairpin stub of the same inductance for modeling.

With 450 MHz dipole you will "research" this subject faster by taking piece of wire or tubing, make about 3 turns in the middle, put the dipole up, measure the resonant frequency and then snip the ends untill you get it where you want it. Fine tuning can be done by squeezing or expanding the coil turns.

To make it more efficient, you can just bend the ends 90 deg. in L or T shape, instead of using coils.

Note:
"I use it with a tuner on 40 thru 10 with very good results. I highly recommend it."

This is no indication of performance. As Cebik says: " Swr does not indicate what the antenna is doing, only what the feedline is doing".

High losses will show up as low SWR!. This gimmik antenna is not worth putting up.

Source record: 96656

The only critical length of a dipole is the end-to-end length. The length
of the loading coil when inserted in the antenna should not affect this.

Locate the centre of the loading coil at the point where it is supposed to
be along the antenna and reduce the lengths of the antenna elements on
either side of it by half of the length of the coil.

In other words, the total reduction in length of the antenna elements is
equal to the coil length, leaving the original dipole end-to-end length
unchanged.

Reg, G4FGQ

If you say a 6000 ohm feedpoint is resonant. I personally call that
the (anti)resonant point.

> Tell me that longer is better, at least when it comes in multiples.

You will be able to use the longer dipole on 75m. It will be about
one-wavelength long on 40m which gives some broadside gain over a
1/2WL dipole. But the feedpoint impedance on 40m will be so high
you will need to avoid coax and feed it with some variation of
ladder-line.

A one-wavelength dipole has about 2 dB gain over a 1/2WL
dipole at the expense of other directions assuming a
height of 1/2WL+.

He's defining "resonant" as no reflections. Instead of a
standing-wave antenna, he is sacrificing half his power
(or more) in the resistors to avoid reflections and turning
the antenna into a traveling-wave antenna.

It's somewhat like a terminated-V antenna, described in the
ARRL Antenna Book.

> (1) What are the drawbacks to this antenna?

He is losing at least half his power in the resistors.
Wouldn't you rather radiate that power? I go to great
lengths to obtain an extra 1 dB.

> (2) What is the feedline?

With a 9:1 balun, it can be coax since there are so few
reflections.

After I posted that, I found out that the link was no longer any good. I have the Imax 2000 and have used it on the band it was designed for (CB) an it works great. It's withstood many strong storms when I lived in RI and here on the coast of NJ. I've tested it with my MFJ antenna analyzer and it shows an SWR of less than 2.0 from 10 to 12 meters. When hooking it up to my FT-100D, I could pull in a lot of DX stations on 10m with it. One day I might actually have a chance to transmit with it on 10m! :)

If I remember my traveling wave antenna theory, he wouldn't necessarily be loosing 3 dB in the resistors. At higher frequencies more of the power radiates before it gets to the loads, does it not?

Source record: 96662

Though I haven't actually done this, the way I'd approach it is to determine the desired resonant frequency of that element, standing alone. It's not so much the length of the element as the element's reactance at the operating frequency that's important, and if you make an element the same diameter and length as in the simulation, and trim the coil so that your physical element resonates at the same frequency as the one in the model, you should be OK. That's my reasoned approach, but for sure listen to those with experience before taking my advice on it. You should be able to determine the resonant frequency by modelling just that element separately, with a source somewhere near the center.

When you posted earlier about your shrunken design, I had the mental image of a loading coil in each side of the element, and the other poster's comment about using a shorted stub shorter than 1/4 wave to get the same inductive reactance gave me the idea for what should be a pretty rugged, and easy to build, way of doing it...the center of the element would be tubing, and the ends would be rod. The rod would go into the tubing, forming the coax stub on each side. They could screw in, so you could store the antenna in a very small space. I don't recall ever seeing such a design, but it should work, and avoids the trouble of coming up with a good mechanical arrangement for the loading coils. Same thing could be done for shortened-element HF beams, too.

Cheers,
Tom

Hi Jim,

You are right (losing - unless it has diarrhea). What is described is a vertical, half Rhombic, a Military application for many years. This report appears to be about a design from yet another "inventor" who has "discovered" something that confounds the experts.

The original poster asked for comments, especially about the resistor (the difference between shorting it and loading it) however, nothing is said about ground. Both of the resistors will require radials, however, there seem to be more specifics missing than that.

In other words, what is the leg angle subtended at the fed point? Why not simply feed one end and terminate the other? Seems like a pain to elevate the feed point without some analysis showing why - but then it appears the column was painfully shy of anything technical beyond carpenter scaling.

Yes, "more" but not near 100%. A multi-wavelength terminated rhombic
loses its reverse radiated lobes and along with them, quite a bit
of power. Even on 10m, 110 ft. is only 3 wavelengths long. Averaged
over all of HF, I'll bet that antenna loses close to half of its power
in the resistors, assuming all reflections have been eliminated by
the resistors.

Apparently, most of the initial experimental data was collected during many long hours of testing at the Murphy's Tavern field laboratory using Murphy's "Ice Cold Beer" sign.

In a standing wave antenna, like a dipole, the power wave hits
the end of the antenna and voltage and current are reflected.
The standing wave pattern on 1/2 of a dipole looks somewhat
like the standing wave pattern for a lossy 1/4WL open stub.
In the case of a traveling wave antenna, the power wave hits
a resistor with close to the same value as the Z0 of the
antenna and is dissipated in the resistor.

So, a traveling-wave antenna is essentially one without
reflections.

So "Swarming" is really the term for that? I could use that.
Sometimes that phenomenon is real comedy material. I can just
see Laurel and Hardy putting up a short wave antenna......

"swarming" hmmmmm, like you disturbed a hornets nest eh?

Now that I think of it, the actual physics behind "swarming"
would be pretty darn sophisticated stuff.....

What is need is some kind of "brain washing" technique for wire....

Either that or they should sell wire in straight lengths.....
One of my favorite (and boring) routines at the Home Depot, while awkwardly tooling around with 20 Foot pipes in the shopping cart nearly causing bodily harm when negotiating a turn down an isle, is to ask one of the managers, "where do you keep the 1000 footers?"

Getting home with a 500 foot straight length of wire would require a few red flags in back.....

Doc,

Would this be a good reason to use solid core copper wire?

After tying one end of my ladder line to a short (PVC) pole at the house roof peak (this is to keep it high and away from some other lines), I need to carefully arch (arc) it around and into the side of the house (or into a modified "window" that ventillates the attic space up there. I might use a "stick" or something to make sure the ladder line stays where I want it here. The ladder line at this point has to go through a space between a cable tv and a telephone line. If the ladder line is kept in place, it will be 2-3 feet away from the other lines which are perpendicular (and thus only in proximity at a one point).

It is because of these other lines that I perhaps might have to consider other alternatives, but I thought I would first try the idea of running the ladder line all the way into the station in the house. If there is a problem with interference, then I might have to consider the system, I have seen mentioned, where you run double coax lines into the house for the last section with the shields tied together (anyone actually tried that, does that work well, any problems, etc.?)

My point being that solid core wire is easier to "mold" into shape. My only concern is that sometimes solid core could break if there is a repetitive friction type bending stress along the way (wind, or who knows).

A Traveling-wave antenna is used for satellite up-link communication. The signal is a microwave frequency up into the (multi) GHz region of radio waves. The transmitting tube is a traveling-wave tube, which is powered by a special pulsed amplifier.

A familiar use for this set-up is to relay telephone signals (from U S Sprint, etc.) up to the satellite and then down load to another ground station where the signal is converted back into a telephone signal and sent (over land line) to the person you called. This eliminates the use of land-lines most of the way for your long-distance telephone calls.

There are also many military uses for this type of technology.

By the way, the signals are fed from the amplifier through Wave-guides (a hollow rectangular cross-section sections that are held together by flanges), rather than by wires. It would be similar to a squared-off hose section, connected to other hose sections, if this makes the concept easier to understand.

Waveguides have much less loss than wire or cable and because of the ultra-high frequencies involved, are much more efficient.

Hopes this gives you some idea of this type of communication.

Regards

warren

Jopl wrote:
"What is a traveling-wave antenna?"

A traveling-wave antenna has only weak if any reflections. So, it is defined.

A traveling-wave antenna is the opposite of a standing-wave antenna. In a standing-wave antenna, the wave reaches the tip end to find an impedance significantly different from the characteristic impedance of the wire or wires carrying the wave.

In the standing-wave antenna, the wave often encounters a short-circuit or an open-circuit at the antenna tip which reflects 100% of the energy remaining in the wave after its trip from the feedpoint. This produces a standing wave pattern on the anternna wire just as a short or open would cause on a lossy trannsmission line. In the standing-wave antenna case, most of the energy escaping from a good antenna is radiated as r-f in place of being converted to heat at the wire.

A traveling-wave antenna is usually equipped with a resistor or resistors to absorb energy which is not radiated on its trip to the end or ends of the wire or wires (if it is a balanced antenna). To absorb 100% of the remaining energy and to produce no reflection requires the chosen load resistance to match the charcateristic impedance of the wire, or wires in a balanced configuration, of the antenna.

The ideal horizontal rhombic antenna, for example, is a balanced traveling-wave antenna which is terminated at its far end with a resistor equal to the characteristic resistance of the antenna at its far end so that no energy will be reflected at the far end to travel back toward te feedpoint and produce radiation toward the feedpoint end of the antenna. Well constructed and with the proper termination resistor, the rhombic is unidirectional. Without the resistor, the rhombic is bidirectional and its front to back ratio depends on how many wavelengths are in a side of the antenna.

The ideal dipole antenna, for example, is a balanced standing-wave antenna which is terminated at its far end in an open-circuit in the usual case, or it is terminated in a short-circuit if the dipole is the "folded-dipole" type. Both types radiate identically. Only the drivepoint resistance is different between the two types of dipoles. Both dipoles have energy left over from the first trip between feedpoint and antenna tip and this is nearly 100% reflected at the tip. If the dipole has a 1/4-wave length between drivepoint and tip, the open or short is inverted and at the feedpoint the open-circuit tip appears a low impedance. On the contrary, the short-circuit at the tips of the

folded dipole appear as a high impedance back at the feedpoint when the elements are 1/4-wavelength.

The usual horizontal balanced rhombic looks like a transmission line of 600-900-ohm Zo. It is pulled apart for extremely wide-spacing which allows radiation. This widening as distance from the drivepoint increases also raises the Zo to a high value but this is symmetrically reduced back to the drivepoint impedance by the reduction in spacing between the rhombic wires toward the far end. Ideally the whole assembly just looks like a transmission line terminated in its Zo, which happens to have a wide spot within which allows radiation in and out. At high frequencies where the rhombic has many wavelengths per side, much of energy fed a rhombic will be radiated before reaching the termination, often a dissipation line made from stainless steel resistance wire.

Best regards, Richard Harrison, KB5WZI

Hi Lorenz. The R7 will work, needs a ground radial system to work well, and will be difficult to get a good match on multibands. Never used one myself, just commenting on multiband verticals in general that I have used.

Fritz,
I have an R-7 currently laying in the yard. I'm not
a big vertical fan, but have to say that it did work as
advertised. Unfortunately, the fibreglass insulator used
to hold the antenna on the 'base' doesn't last forever if
it's in the sun very much (mine was).
It wasn't really all that hard to tune, just follow the
recomendations. Don't expect much bandwidth on 40 meters!
It's also fairly sensitive to 'where/how' you mount it.
I tuned mine on a fence post, then tried to move it to the
top of my house. Worked great on the post, terrible on the
roof. Too lazy to re-tune, so just mounted it on the post.
Still not a vertical fan, but I think I got my money's
worth out of the R-7 (10-15 years?).

> --> sed 2,4s/=//g signature "I hate spam!!"

I picked one up used. I checked out all the mechanical
connections in the traps, then set it up according to instructions manual
and am terribly pleased with it. I did arrange for the 40 meters to
be set to the low end where I operate, other than that, I get great
results with it using QRP. If you do a Google search you will find that
some people have experienced problems, but nothing that can't be fixed
using the information available on the net. I have mine sitting on a
12 foot piece of pipe just to lift the radials over the garage roof.

833. Re: Experience with Cushcraft R7 vertical HF antenna?

Newsgroup: rec.radio.amateur.antenna
Date: 2004-04-15 23:22:39 UTC
From: Incognito <BLB@sero.net>
Message-ID: <3PEfc.8101$432.7574@fed1read01>
Source record: 96584

Well the R7 Cushcraft antenna is NOT your Fathers quarter wave vertical --
it is a half wave end fed antenna thus it needs no radials. It is fed at a
high impedance point by virtue of the matching black box at the antenna
feedpoint.

In fact the addition of radials will really screw it up --- read the manual
see URL:
http://www.cushcraft.com/support/pdf/r7.pdf
"THE R7 SHOULD NOT BE CONNECTED TO A GROUND RADIAL SYSTEM".
I ignored this (as an experiment) and found Cushcraft knew what they were
talking about.

The four 49 inch rods at the antenna bottom are counterpoises designed to
isolate the antenna from ground and not long enough to be resonant on any
band.

The bandwidth and efficiency on 40M, I found to be poor. But it works well
enough on the other bands, covering full bandwidth on all bands except 40M
and 20M. You will have to choose the portion of the band you want to operate
on for these two bands.

Tuning the R7 was easy, following the manual instructions.

Be careful of running high power into this antenna for an extended length of
time -- particularly if you horse it beyond resonance with a tuner --
several here have frazzled the traps when doing this.

Using an R7 I was able to work a lot of DX, it does seem to have a low angle
of radiation -- Cushcraft claims 16 degrees.

For more opinions --see url:
http://www.eham.net/reviews/detail/518

This opinion is not to engage in a debate of 1/4 wave vs 1/2 wave verticals
save that for another thread.

I fail to see that answers my question. Which was and is just how is
the pattern of a ï¿½-wave dipole different than a full-wave dipole?

I know the answer, base upon you response to the original question I
wonder if you do.

However, because of you refusal to include the portion of the previous
message that you responding too in your postings (normal N/G
etiquette) it is difficult to be sure what you are talking about.

Dick,

I challenge any antenna 'inventor' to invent an antenna that is not described in Kraus' book, at least at the fundamental theory level! Haven't seen one yet and I've been reading QST for over 30 years (not to mention my dad's collection that goes back to 1942).

By the way, I 'invented' an interesting antenna several years ago, which I call the half-quad. The best way to describe it is dto picture a diamond shape quad, fed at the side corner, half buried in the ground. Shows some interesting patterns on the good ol' AO program. I came up with a three element version with one feed point (center element). You can change directions by switching a capacitor or inductor in and out of the two 'outside' elements. It didn't use terminating resistors. I couldn't get a multiband version to work. (and, no, I haven't built it yet)

> coax.

The impedance will still be 50-to-70 ohms if you add the extra
half-wavelength to just one end of the antenna.
i.e. The wire on one side of the antenna feed point (coax connection) is
still 32.5 feet, and the wire on the other side would be 65' + 32.5' plus
another 3.3', since there is no end-effect on the extra half-wavelength of
wire you are adding. So actually, one side is 32.5 feet and the other side
is 100.8 feet. You should get almost 2 db of gain in four directions (a
"cloverleaf") by doing that. You will also get a significant reduction in
signal strength (a "null") broadside to the antenna and off the ends. I used
a dipole like that for years in Florida where one of the gain lobes was NE
and the nulls cut out a lot of the stateside QRM for me during European
contests. The full-wave dipole was up about a half-wavelength (65 feet), so
I used RG59 (75 ohm) coax instead of RG58 (50 ohm) coax, and had a good
match. No balun was needed.

Has anyone actually tried it yet?

Considering only a drop in a neon sign or vapor lamp makes the
difference between not working at radiating a tremendous amount of
energy, it's worth a few careful experiments.

Actually, it may be closer to 100 ohms. It's an OCF somewhat like
a "Windom" fed with two-conductor transmission line. The "Windom"
is supposed to have a feedpoint around 300 ohms.

It's an interesting OCF antenna but probably subject to common
mode currents unless an excellent choke is used at the feedpoint.

> You should get almost 2 db of gain in four directions (a
> "cloverleaf") by doing that.

Since it's a one-wavelength antenna, it won't quite achieve a
cloverleaf pattern. It's about the same gain as a 1/2WL dipole
(6 dBi) but with a much wider horizontal beamwidth. For a 130
ft. long antenna, the cloverleaf pattern develops around 10 MHz.

If I understand your description correctly, I'd be highly suspicious of the results from AO or any other MININEC-based program because of the antenna's relatively low height. I recommend that you model the antenna with an NEC-2 based program using the Sommerfeld ground model (called "high-accuracy" ground in EZNEC) -- otherwise you might be pretty disappointed when you actually build it. Be sure to make note of the strength of the pattern as well as the shape of the NEC-2 program results, unless you're using the antenna only for receiving.

After investigating a large set of traveling wave antennas (not Beverage) I think that the smallest amount of power dissipated in the terminating resistance was about 2 db. Mind, these were antennas with useful lengths and angles. It is likely that a rhombic with very long leg lengths would dissipate even less in its termination resistance. For amusement, I will have a look some time. One needs a lot of segments to simulate a three wire, ten wavelength rhombic!
The antenna in question can be a useful expedient in exigent circumstances.

Well, remember the posting that kicked off this discussion was about
the following very short traveling-wave antenna:

"It is a military inverted-V, 110 ft. long total, with each end
terminated in a 150 ohm resistor driven into the ground, center fed
through a 9:1 balun."

A 110 ft. center-fed inverted-V is certainly going to have extensive
losses in the resistors on most HF bands. After all, it is less than
1/2WL long on 75m and only 3 wavelengths long on 10m.

I have a spool of 300 ohm antenna feed line out in the barn, never been used. Probably enough there for some kind of antenna, I will have to unspool it and see how much is there. Anyone have anything good to say about those folded dipoles that use this 300 ohm line for both the antenna and the feed line? I have seen illustrations of folded dipoles using this, but in actual practice this line will naturally have some twising when it is suspended. I cannot imagine how you would keep it from doing this to some extent. What effect would this twisting have on the effectiveness of the antenna. The illustrations always show them geometrically perfect and straight and parallel.

Bill

Hi Bill,

Nope, not for both - hardly for either (and it is arguable that its Z
even comes close to 300 Ohms). No reason not to try either.

Keeps it from thrashing in the wind. As far as noise pick-up, the
twist (used by the power company) reduces that too. Insofar as its
intended purpose - no effect, detrimental or beneficial.

Hi Ivan,

Ronold King covered this design in spades in his work "Antennas in Matter" (I may have the title wrong, my references are packed away following a recent move). Only 600 or 700 pages of antennas immersed in water (and earth, I believe) to reveal no particular advantage (and as one might imagine, many very specific, particular disadvantages).

Hi Bill,

Used just such an antenna a long time ago, Worked great.. and was
cheap to make.. Problems that take some engineering :)

300 ohm line is not strong thus it will break either due to wind
action or smiply from weight of snow or ice if not well supported. .

you'll need a good method of supporting the connections at the center.

when wet resonant frequency will change.. lower if I remeber
correctly.

you'll most likely need a tuner -- or an old tube rig like we used
that wasn't that fussy about SWR.

Power limited to about 200watts.. safely. Less if not tuned exactly
or if line is wet.

there is not much advantage over an ordinary dipole.. it is for the
most part a single band antenna. But can be used like a dipole on 3rd
harmonic.

My recomendation put up a regular dipole , feed it with the 300 ohm
stuff and a good balanced tuner.. you'll get more milage that way.

Dan & CW,
This may help understand 'how' I post, probably won't excuse any percieved 'mistakes' in the procedure, but at least you'll understand. I use a 'newsgroup' reader, it shows each thread and each response in a thread, and everything progrsses in a very logical manner. One of these 'newsgroup' readers is provided in Netscape and IE. I see no point in repeating what is already 'there' for anyone to see (if they use a NGreader, of course). I have to assume that you don't, too bad.
As for the radiation pattern differences between a 1/2 wave and full wave antenna, a specific explanation would be kind'a difficult because more than the 'length' can make a difference, height, environment, other antennas, etc. But, in general, the usual higher angles of radiation are more pronounced, and the pattern is 'sort of' sharper (if that makes any sense) for the full wave dipole. It's easy to see than to describe if you use a modeling program, or the usual radiation pattern diagrams in the antenna books. This also depends on the antenna's height, what I attempted to describe
is at more than a 1/2 wave above ground. Being lower than a 1/2 wave above ground makes for even greater differences.
I hope that convinces you that I might have at least a faint idea of what's happening...

Andy,
True, for the most part. But I was 'assuming' a center fed doublet, not an off center fed one. (To cover all the possibilities would mean more 'work' than I'm willing to put into a 'simple' answer.) Both of us are 'right'.
'Doc

PS - I used an antenna something like what you described at one time. Fed with ladder line through a tuner, it loaded like a dream on all bands! Had a really 'crappy' pattern for the use I wanted to put it (couldn't rearrange how it was errected), so I went back to the 'loop'. Oh well...

Bill,
If you like 'playing' with antennas, why not try it? I
doubt if you'll see any great difference in performance from
a 'normal' dipole, and matching the '300' ohm feed line will
be 'fun', but certainly 'do-able'.
The usual 300 ohm twin lead that you find has certain
problems when used for an antenna for the lower frequencies.
Mechanical problems, as in strength (which has already been
mentioned). Not really ~that~ big'a problem, but one you should
be aware of. Twisting the line won't cause any problems and may
relieve one, 'flopping' around in wind (also pointed out). Ever
seen one of the twisted 'streamers' used in advertising tear
it's
self apart? Well, very often, anyway?
Using a tuner (I know Cecil, but for me it's easier) to feed
the folded dipole will make things 'more sinple'

I use the Netscape newsreader but it is more convenient
for me to sort by date rather than by thread. Therefore,
I don't know to whom you are replying unless you quote
the attributions and understanding the context of
your postings is quite often difficult for me.

The FW dipole I used for years had a 1.2:1 SWR, fed with RG59 and no balun.

Never saw an indication that the feed line was radiating. On my many dipole versions, I have tried them with and without baluns. If the resonance of the antenna didn't change with the balun in, I figured the balun wasn't needed. On one, where the coax could not come off perpendicular to the dipole, the balun did raise the resonance frequency - suggesting the feedline was radiating without the balun in. That same W2AU balun caused havoc with TVs in my neighborhood when I used it for ten meter operation. I assumed the core was saturating and causing the harmonics. For that reason, I don't use baluns just for good measure; only when I need the matching (4:1 baluns) or when there is some indication that the feedline is radiating. Plus, baluns add weight to the antenna, loss to the power, and are susceptible to weather problems.

The 2db gain was what the ARRL Antenna Book (1964 vintage, p. 142) was calling out for a FW collinear array gain. Actually, the FW dipole fed at the current node would be like a 1-wavelength long longwire (a short longwire?), and the Antenna Book shows a negligible 1/2 db gain (p. 170 on "Long-Wire Antennas") over the dipole gain. The cloverleaf assertion was based the Antenna Book radiation patterns shown on p. 39 (Fig 2-16) and the discussion of "How Patterns are Formed", as well as p. 59 (Fig 2-74b) showing the FW pattern distortion caused by end feeding.

Okay, I'm compelled to chime in on this one.

The ARRL antenna book has a "cookbook" design for using 300 ohm twinlead to make folded dipoles. In my 18th edition its the first thing in Chapter 15 "Portable Antennas", pg 15-1.

It uses an open stub of the same 300 ohm twinlead to match to a 50 ohm coax. You could just as easily omit the stub and run the twinlead to a tuner.

I have one made from Radio Shack 300 ohm wire. After cutting per the cookbook, including the stub, it tunes up perfectly on 3.775, only 25 kc up from the stated center frequency.

The drawbacks to the design:
1)The stub, which is 37 feet long for 80 meters. You can replace the stub with a capacitor, but I had the twinlead on hand....and was interested in the design.

2)The fragility of the twinlead. Dave, KC1DI, mentioned that in his post too. I have the center taped to a foot-long chunk of electrical PVC, and a bit of nylon cord helping to support the feedline drop. That's been sufficient for two years, so far.

3)Power. I have no idea if this thing would stand up to a kilowatt, but it works fine at 100 watts. I'd be afraid to "smoke test" it....

Twisting, flopping, and drooping seem to make no difference. It plays as well as the inverted vee it replaced, but except for a better SWR bandwidth, its just a dipole. With the stub match, and a 90 foot coax run back to the shack, the SWR is under 2:1 from about 3625 to about 3910, but my rig's internal tuner handles the edges easily. The SWR seems to rise more sharply on the higher end of the band. I don't notice any changes in SWR when its wet--not yet anyway.

On the positive side, the antenna is relatively light, and you can drop the 300 ohm feeder right to ground level rather than pulling 20 lbs of coax 40 feet up. And if you have a spool of twinlead sitting around--its free.

I keep mine because its already in place, and it works. When it falls out of the tree, I might follow Dave's advice and put up a regular dipole fed with the twinlead.

Its only unique quality is a slightly wider SWR bandwidth.

Have fun..

It still may have had a feedpoint impedance of ~100 ohms. RG59's
Z0 is 75 ohms, close to what you would need to transform 100 ohms
to 50 ohms. An odd number of 1/4WLs of RG59 will transform 100 ohms
to 57 ohms, neglecting losses.

> Never saw an indication that the feed line was radiating.

We can mount a logical argument that since the feedpoint
impedance looking in each direction is different, the
currents have to be unbalanced resulting in feedline
radiation.

EZNEC says that it is somewhat of a square pattern where the "corners"
of the square are just barely starting to form a cloverleaf. The "nulls"
off the ends are only 3 dB down. I suspect there was a lot of guessing
about radiation patterns in 1964. Some say there still is a lot of
guessing. :-)

Just modeled the subject antenna as well as I can. Without the
termination resistors, the antenna has a gain of +6 dBi on 3.8
MHz. With the termination resistors, according to EZNEC, the
gain drops to -10 dBi, a difference of 16 dB.

Hi Gang

Since the radiation of an antenna is done primarily on the surface of the elements (or wire) would gold plating the elements increase the efficiency of the antenna in any way?

Gold sounds expensive, but if thin enough, one ounce of gold could plate an entire football field. Brass corrods, nickel is usually used as the first plating before another metal like gold is plated over that. If the cost for gold over the cost of brass is only about 1 buck per foot of element length, making cost not relavent to the question. Would a gold plated antenna work better than aluminum or nickel plated?

I too use a reader as I believe everyone else does, however, rather than clutter up my screen with old obsolete messages I us an option of my reader that lists only the new unread messages.

Additionally, there are at times multiple replies to a thread and your posting may be listed several messages below the one you are replying to and it can be anyone's guess which one it was.

Thirdly, for anyone reading the news group archives and trying to follow anything you have posted is near to impossible as the archive listing can be by the poster and not the thread.

Lastly, news group etiquette was setup of a good reason. Following those suggestions allows for a minimum of confusion.

Please think about this. Of course, if you just want to be contrary then have fun.

Why don't you download the demo version of eznec, www.eznec.com/, model
an antenna with gold, copper, aluminum, etc. and see for yourself how
much difference it makes?

Of Course - you knew that anyway. How much? More than a dB? No.
Less than a dB? Very much less.

-Unless-

>Gold sounds expensive, but if thin enough, one ounce of gold could
>plate an entire football field.

I know you didn't really have this in mind, but putting your gold into
System loss pays back far more than trying to raise the efficiency of
the radiator from 99.89% to 99.90%

Gold plate your lawn and you could easily recover 1dB in a DX lobe.

Warren wrote:
"A traveling-wave antenna is used for satellite up-link communication."

The similarity between the "traveling wave tube" and the "traveling wave antenna" is that both are wideband devices.

The helical beam antenna is not considered a traveling wave antenna, though it does enjoy a wideband response. The traveling wave tube also employs a helix and enjoys a wideband response but is not usually an antenna.

Many microwave amplifiers are capable of only 1% of the center frequency bandwidth. The traveling wave tube was developed to give more than 10% bandwidth. It was invented in England in 1943.

The traveling wave amplifier generates an electron beam similar to that of a CRT, but the beam is confined within a long helix. The signal input is to the electron gun end of the helix. The signal output is taken from the collector end of the helix.

The traveling wave amplifier electrons are modulated by the signal traveling along the surface of the helix. Interaction between electrons in the cathode beam and signal on the helix promotes signal growth and accumulation as the signal travels to the output end of the helix.

John D. Kraus, inventor of the monofilar axial-mode helical antenna (helical beam antenna) notes that it: "---has inherent broadband properties, posessing desirable pattern, impedance and polarization characteristics over a wide frequency range." (page 268, 3rd edition of "Antennas")

Kraus` 1948 helix had a pitch angle of 14-degrees, 6 turns, 0.31 wavelength diameter, and a center frequency of 400 MHz. Its pattern was satisfactory over the 300 to 500 MHz range.

Kraus says:
"Although the helical beam antenna consists of a continuous conductor carrying a traveling wave, it is also a periodic structure with period equal to the turn spacing as considered in Sect.8-8. (page 271, 3rd edition of "Antennas)

>especially as a restricted space antenna.

Hi Trevor,

It looks like it would be 2-5% efficient at 80M to 20-50% efficient at
the higher bands. Your full size dipole or monopole with a ground
radial system of 8-10 10M wires would start at 50% (or better).

Efficiency isn't the entire picture; how close to ground is another.
In other words, once your efficiency got you out beyond the radiator,
what is the ground loss look like? The closer you are, the worse.
Get it up high and things may work quite well. The difference between
full sized and this may be a couple of S-Units (better than the
difference being many S-Units) for the low band.

That might not be a fair comparison, since the pattern might be quite different with and without the resistors. To determine what fraction of the applied power is dissipated in the resistors, simply click the Load Dat button.

I've seen real-life cases with high-Q microstrip structures where gold plating actually caused a significant lowering of efficiency. As you point out, nickel is used as a barrier metal to prevent alloying of the gold with the underlying copper. If the gold isn't at least several skin depths thick, significant current flows in the nickel. Nickel is a particularly poor RF conductor, very much worse than copper, because the skin depth in nickel is decreased dramatically by its ferromagnetic permeability. So, if you're able to calculate skin depth, and know what you're doing, and are willing to use quite a bit of gold (particularly necessary at HF and below) you can achieve efficiency with gold plating that's pretty much indistinguishable from that of copper. If you don't know what you're doing, it is possible to substantially degrade the efficiency by gold plating. I'm sure somebody could be conned into buying one, though.

Well, the shape of the pattern looks the same. The Load Dat function
produces 3015 watts into the antenna (high feedpoint impedance) and
1399 watts dissipated in each resistor. That's 217 watts not dissipated
in the resistors out of 3015 watts into the antenna for an efficiency
of about 7.2%, in the neighborhood of a mobile antenna on 75m.

Well, the FW dipole may not have had all the advantages I thought it did -
but it worked well enough that I stopped bothering with the 2-element wire
beam on 40m for the contests. It's a bit like fishing - if you believe in
your equipment you will usually do better than if you don't. HI

It's not a bad antenna and I didn't mean to knock it. I like
that 40m pattern where it has 280 degrees of beamwidth. It's
actually better than a cloverleaf beamwidth pattern.

Hi Roy;
It's worse than that: Copper will diffuse throught the gold and pile up on the surface.
I showed that with an Auger microprobe at Motorola decades ago.
So to go to a gold surface, nickel is mandatory, then a thick gold coating;
Too expensive!
It's not like the switch from aluminum to copper, which is a 2x resistivity improvement.
You just can't beat plain old copper.

I am planning on constructing a satellite antenna for feild day this year

Having worked UO-14, AO-27, ISS, etc, i know what it takes to do it but never have really done much portable work lately, not since UO-14 went down. i know AO-27 and SO-50 are alot weeker. ISS should be easy if they are active.

The antenna i am planning on constructing is a quad antenna. 4 elements on 70cm (435Mhz) and 3 elements (145Mhz).

I worked out the math for them, and i know everything should fit on a 40 inch boom with some space to spare.

Any tips on its construction. I have not built a quad before, but have constucted almost every other antenna type related for LEO satellites

i have an abundant supply of bamboo or should i use PVC instead. i plan to use 16GA copper wire for its construction and N type connectors

the finished antenna most likely will be setup on a camcorder tripod for feild day

the one question i really have, is should i bother with any type of matching circuit. I have calculated the SWR to be pretty good at specified freqs, but should i try for anything better than a 1.7:1 ratio.?

thanks in advance for any tips you give,

Steve KC2GOG

The antenna described in this thread has been utilized by the military for simple, easy to erect and fairly inexpensive field use.

I don't think that you will get any argument from anyone that a resistance terminated antenna is not as efficient as a tuned dipole. The benefit one receives from using a resistance terminated antenna is the lack of having to use an antenna tuner (another misnomer) when operating off resonance. I, personally, use a B&W folded resistance terminated antenna. This antenna is far from efficient but I can make great changes in operating frequency with out having to worry about matching the final circuit to the antenna.

I would like to have a tuned dipole for each band/subband but have neither the room nor the desire to do so.
Now if you go to the receiver and look at the signal strength meter, s-meter, you will see that 16db is only about 1 to 1 1/2 s units. In that a receiver can differentiate a signal down to a very small value the loss is of only academic interest, except to the purists.

Any tips on its construction. I have not built a quad before,

If you are just going to use the quad on Field Day and are not planning on a long term installation, a cheap way to go is use PVC for the boom, and 1/4" or 3/8" wood dowel for the spreaders. May cost $5 at Home Depot. If you want something that will take weather better, use UV resistant PVC and 1/4" fiberglass rods for the spreaders.
As for the 1:7 swr, I would not worry. But, if you are a purist, there are several ways to reduce that if you want to go to the trouble.

>for simple, easy to erect and fairly inexpensive field use.

Yes that is very true. However, what the military needs, and what us hams are trying to do is not that similar. What I would like as a ham is 100% of my rf radiated, especially when I am mobile. The military wants to communicate, and they don't care how the efficiency of the antenna system factors in to all this.
In an old textbook of mine, the military wanted an automatic antenna tuner that would match 20KW to a 35' whip 2-30 MHZ. At 2MHZ the whip was very inefficient, and probably glowed in the dark. But they could communicate by the brute force method. I guess it depends on whether your goal is just to communicate, or communicate the most efficient way.

Relative Conductivities:

Copper 1.00
Aluminum 0.61
Gold 0.706
Nickel 0.198

Now what is IM??

Have you ever check the calibration of your S-meter? I have never
found one that was 6dB per S-unit. Most seem to be around 3ï¿½-dB. Using
that yard stick 16 dB is 4ï¿½ S-units. Many would consider that
subatantial.

Gang:

Way back in the 60s, I think, there was a very thorough research article in JIEE (Aust.) about RF skin conductivity of various practical metals. Oxygen Free High Conductivity (OFHC) Copper won hands down. Until you heat it, bend it, or look at it cross-eyed, that is. Silver plate is next best, but only if it is hard Silver, not cosmetic Silver which is what you get at your local plating shop. Hard Silver plate is difficult to come by, and uses chemicals which I'm guessing have since been banned by EPA. In my day (1960), hard Silver plate with a Rhodium flash was the most practical high RF conductivity process available. Nowadays, who knows?

Hi All,

It hardly matters unless you are speaking of switch contacts.
Insulated wire's insulation is absolutely unconductive, and yet in the
context of antennas it doesn't impact the wire's capacity to carry
current.

Oxidation products only become a problem at interfaces where they
either resist current between the joined conductors, or create a
semiconducting barrier.

The technician is taught to clean surfaces of tarnish to bring bright
metal into contact. Then crimp them (or twist the wire - same thing)
for a gas tight seal. Then solder them to weather proof the seal
(solder is never meant to be a mechanical join or the conductive
path). Common practice allows for solder to provide more
functionality than what I describe - this does not elevate the method.
Barring the final solder, switch contact faces must meet the same
conditions of bright metal and gas tight seals. This is often
achieved by pressure (some mistake the so-called "wiping" action as
meaning to scrub the oxide away - a useful metaphor but only that;
otherwise switches would self demolish in very few operations) and a
sustaining current (wet vs. dry contacts).

A hundred bucks says you haven't checked your rig's S-meter response to two signals accurately measured as 16 dB different.

16 dB is the approximate gain of a 23 element Yagi having a 6.5 wavelength long boom (that's about 450 feet at 14 MHz), compared to a dipole. Only "Kurt Sterba" and a few others believe this amount of gain is insignificant.

Well, the average ham receiver's S-units are more like 4-5 dB steps.
Even with the "standard" 6 dB per S-unit, 16 dB is about 2.7
S-units. I guess there are a lot of purist hams, me included.

Message-ID: <3200347.0404161954.4f792f7b@posting.google.com>
Source record: 96549

Hmmm...My book says aluminum's resistivity is about 2.6 microohm-cm,
and copper's is 1.7, only a 1.5:1 ratio--though it may not be quite
that good for commonly used aluminum alloys. OTOH, copper also
suffers from being alloyed. But in any event, it's good to keep in
mind that the RF resistance ratio for non-magnetic materials goes as
the square root of the bulk resistivity ratio, because higher
resistivity materials have larger skin depth. So a 2:1 ratio at DC
ends up being only 1.41:1 at RF, and 1.5:1 at DC is only a bit over
1.2:1 at RF.

Since both copper and aluminum have good conductivity, it's just not
worth sweating in practically all cases, unless the antenna is very
short (and thus has very low feedpoint radiation resistance).

Actually, what I thought Gary might be getting at is the protection
from corrosion that gold might offer, as compared with bare copper.
I'd say that it IS worth worrying about protecting your antenna from
corrosion. Maybe you just have to think about it long enough to
understand that you are lucky to live in a place where corrosion isn't
a problem, or maybe you live next to the ocean where salt spray will
get the best of almost anything metallic. But like Roy says, gold
over nickel is probably a bad idea. Unplated stainless steel antenna
wire is probably a bad idea. Painted copper pipe, or anodized
aluminum tubing, will probably work well for a long time.

Cheers,
Tom

haha, good joke.

Advertizing Yagi "Neon" tube arrays as STEALTH antennas.
Your are beating my own inventions of crazy antenna designs.

Won't work too well actually, at least not for reception, because the
irregular flickering of the plasma will induce a very large amount
of noise.

had same problem here also. I found that the 15 meter trap was the problem. take a continuity test from bottom of the 15 meter trap to the top and you will find that is dead short. of course take the trap apart from antenna first, as you will have to take all apart anyway, meaning the heat shrink and all, once that is done you will find 2 screws holding the wire from the trap to the aluminium pipe of the antenna. take a file or sandpaper and clean around the screw connections as that's where corrosion will form. I use Vaseline in putting it back together. check your work as you go along. I found some shrink tubing at home depot, it takes 1 inch diameter and 4 inches long. when all the work was done, trap looks as good as new, and now works.ps..a good set of guys made from heavy fishing line or whipper nipper nylon line, which you can buy in large roll really does keep the thing straight.if you want to see my installation, I can send pics.will never put up a vertical without some sort of support. let me know how you make out.

One place where I can clearly see the difference between copper and aluminum
is comparing my (copper) Nott screwdriver with my (aluminum) Tarheel
screwdriver or my (aluminum) Hi-Q mobile antenna on 20 meters.
Mounted on my Durango, at resonance the Nott's impedance is 9 ohms, while
the Tarheel is 20 ohms and the (smaller tube) Hi-Q is 30 ohms; Measured with
the same whip in all cases.
This is a case of a short antenna.
The difference is significant and easily measured.

That's much, much more difference than can be explained by the different conductivities of the metals. Either some very resistive alloys are involved, or there are differences between the antennas other than the type of metal.

The measurements are reproducible. That's for sure.
And you can bet the aluminum in the Tarheel and Hi-Q are alloys.
Using the Nott (just copper, no plating) I get a 9 ohm load at resonance on 20, 10 ohms on 40 and 80.
With a simple toroidal autoformer the mobile rig sees 50 ohms resistive at resonance on all three bands.

Roy
I looked up the numbers.
The Nott is 2" diameter bare copper 3' long.
The Tarheel is 2" diameter painted aluminum 4' long.
The Hi-Q is 1" diameter powder-coated aluminum 3' long.
I used the same whip for all measurements.
If we take the conductivity of copper to be 100, aluminum is then 60 and aluminum alloys are as low as 30.
That's a factor of two between the Nott and Tarheel and the reduced surface area of the Hi-Q explains the additional resistance there. Considering the difference in surface area and resistivity among the antennas, the measured impedances seem quite reasonable to me.

909. RE; r-7 antenna feedback...

Newsgroup: rec.radio.amateur.antenna
Date: 2004-04-17 12:32:14 UTC
From: Jean-Guy <jglandry50@rogers.com>
Message-ID: <it9gc.167301$SQE.80599@news01.bloor.is.net.cable.rogers.com>
Source record: 96559

I had answered a post earlier this morning about r-7 not resonating
anywhere's but 10 meter.
black box is not at fault, as it works on 10 meter, so antenna is good up to
10 and then high swr on all other bands.
I did say in that post that it was the 15 meter trap,,, sorry but meant 12
meter trap, just a typo, doing this left handed only as I just got out of
surgery to right shoulder, does hamper my typing some, hi hi
also check all other traps to make sure that it is the only one to not work.
funny how a little bit of corrosion will cause a lot of problems.
it was fun fixing after finding problem and has gone thru a tough winter
with strong winds,, all still works good and looks great with guys on it.

thank for reading

Good advice. Only thing I have done different is when putting back together instead of Vaseline I use PermaTex Anti-Seize. It is a good conductor, makes things easy to get apart if you have to do it again and does not deteriorate over time.

Just my two cents worth.

On the other hand, aluminum is lighter. Might be worthwhile to compare the
resistance of an Al and Cu conductors (solid and tube) of the same length
and the same weight. I am pretty sure AL wins at 60 Hz.

Got any idea what the efficiency of your autoformer is?
I'm assuming a single coil for a primary, tapped down for
the load. Would a 4:1 transmission line transformer be more
efficient over all the bands?

I was not suggesting using an entire neon sign or vapor lamp as an antenna. I was pointing out 'the presence of a tiny drop of mercury' is required for these devices to work. A catalyst perhaps?

Therefore, let's say our antenna was a piece of wire or metal tubing was inside another non-metallic tube, and a small amount of mercury was also in the tube. Would the mercury have a desirable effect? Remember, we're not talking about tremendous amounts of power here. Your typical 4' fluorescent tube is a 32 to 40 watt device, and there are much lower output tubes as well. The primary excitation inside the tube is due to high voltage, not high current.

So, it may not be too far fetched to build a few designs and see what performance is observed.

> performance is observed.

Both neon and fluorescent lights work in basically the same way; something
is ionized with high voltage and low pressure and glows.

Neon lights produce light directly from the gas. The color is determined by
the gas. Common gases are neon, argon and krypton.

Fluorescent lights have mercury vapor in them which glows in the
ultraviolet. The inside of the tube is coated with a phosphor which
glows in the visible region when excited by the UV.

Black lights are fluorescent lights without the phosphor.

In either case, the voltage is high and the current is low, meaning the
resistance is high; hardly a good canidate for an antenna element.

Not to mention the small problem that your antenna would contain a
spark gap...

Hi Jim,

100 years ago they all did. And of course, the bands weren't as
crowded then (and VHF started around 2 or 3 MC).

Who would have thought....

919. Re: Tracking down noise

Newsgroup: rec.radio.amateur.antenna
Date: 2004-04-17 16:47:04 UTC
From: zeno <zeno@sonic.net>
Message-ID: <40815F87.887EE63D@sonic.net>
Source record: 96469

Walking around using an old RatShack portable short wave radio I was able to track down an unusual noise source (an incessant clicking that was all over 40-160m. I was able to aim the portable antenna at various wires while walking around. This particular noise turned out to be someone's bad telephone. When the telephone was disconnected, this loud click-click-click disappeared. Seems like that bad telephone was somehow "transmitting" this noise back through the phone lines.

Admittedly the noise from the power lines here are much more difficult to pin down and seems to change with the weather. It can be very annoying and discouraging. There is a high voltage transformer right here next to the house, which means those hv lines are coming right down my driveway. Designing an antenna which is not even close to parallel to these power lines has helped somewhat. I am hoping the new 160m full wave loop which will be further away is going to be a big improvement. I am just hoping that the ladder line feed to this loop will not also pick up the noise. If so I will have to change that feedline to coax which will be a compromise.

Impoving my RF ground and making sure it was totally independent from the A.C. safety ground at the house main has helped also. My primary RF ground cable goes through a hole in the floor at the station and immediately to a copper pipe driven in under the house. This first run is shorter than 6'. This first copper pipe is then tied to several others at about 10' apart to make up for the fact that they are only driven 5' into the ground. Make sure your RF ground is independent of the house AC safety ground. I also use a constant voltage transformer and a good power conditioner because the AC here is a mess.

By the way, I found a very nice and complete listing of conductivities
of aluminum alloys at
http://www.ndt-ed.org/GeneralResources/MaterialProperties/ET/Conductivity_Al.pdf
just after I posted last night. Others may find this useful. Even
the worst of them is not as much as three times the DC resistivity of
the best. So at RF, the worst aluminum alloy will have about twice
the loss of the same diameter copper conductor.

Cheers,
Tom

I did the same thing -- a 10 ft copper clad steel rod driven through a hole in the concrete of my basement floor. The floor is about 5 feet below ground level. I found out later that this was not a great idea because the floor shields the ground below from moisture -- measuring the ground rod to my waterpipe later showed a dc resistance of almost 50 ohms -- it would have made a better dummy load. I have since put 4 10 foot copper clad steel ground rods outside and bonded them together using silver solder. This works much better.

A chum of mine, noting my problematic results, decided to go sideways through his basement concrete intothe back yard where the soil would be moist. The end result was partially flooding his basement after the first rain! He wasn't home at the time!

I should note that the ground rods only provide the safety ground, however they serve as the base for a number of other ground wires spread around the yard in a sort of helter-skelter radial system. This provides a pretty good RF ground.

Hi Bill,

The combination of these two statements could kill you. If AC is a mess, and if you have your own independent ground, then there may come a day when you connect/disconnect a wire between them (and it is guaranteed to be there) that has enough potential to blow your fuse.

Think about it. The most common method of connect/disconnect involves the use of both hands, one wire in each (think of holding onto shelled connectors), with a path across the heart - classic killer scenario.

Having separate grounds is against code. Being against code it is also a loophole for insurance to deny a claim if misfortune comes of this misapplication. Having separate grounds is also bad engineering and bad noise control. In short, there is no good reason to do it when it needs to be done right.

What you have the potential for are problems called "ground loops." Closing or breaking those loops is what brings those problems. There was a thread in the last week with excellent links to how to do it right. I don't have them at hand right now, but you should research or prod me for more.

Hi Bill,

Isolating RF ground from AC ground may be a solution in your individual
circumstance, but it is not recommended or safe under normal conditions.
Single Point Common Ground means what it says and nothing is "isolated".
That begs for problems not the least of which is ground loops.

I do exactly the same thing under my shack WRT multiple RF ground rods as
you have and a very short drop to them as well - that elminates the chance
for 1/4 wave multiples in the ground sytem to raise the impedance
drastically. But according to best available practices and electrical code
everything (antenna ground rods, RF ground rods, and service-mains ground
rod) are all tied together. Understand that this in no way contributes in

any way to "noise" in the receivers, and it can reduce noise significantly. It also helps minimize lightning damage, at least according to all the codes, writings, and many experts in this group.

924. Guy wire vs. guy rope

Newsgroup: rec.radio.amateur.antenna
Date: 2004-04-17 18:14:58 UTC
From: zeno <zeno@sonic.net>
Message-ID: <40817421.ECD12EE1@sonic.net>
Source record: 96474

I am getting ready to put up my masts (5 of them) for a 160m full wave loop. For the most part I am using recycled telescoping tv masts which will be up around 50+ feet. The masts are metal. There will be a pulley at the top of the mast and the antenna will be pulled up with a dacron rope.

The question is what material to use for the guy wires on the masts. Is there a compelling argument not to use wire guys because they might be of lengths that will resonate or otherwise detract from the anticipated effectiveness of this antenna, or is this a non issue, given that the mast is already metal anyway, and the rope to the insulator holding up the antenna wire (#14 hard drawn braided copper) will be approximately 10 feet away from the top of the mast.

Wire for the guys (three sets of four wires, eg. one set for each of the top three tiers) would be easier, and somewhat more permanent than rope. If I were to use the dacron rope for the guys, then I would put up pulleys (that is 12 pulleys just on one mast) so that a new rope could be threaded up there in the future without the mast coming down.

For all practical purposes wire guys would be permanent. If wire is used is it necessary to break up the lengths of the guys with dielectric strain insulators or is this a non-issue with this antenna design.

The physical loop circumscribed by the actual circumstances of mast placement is approx. 588 feet. The loop needs to be about 540 feet, this difference of 48' will be absorbed by the 5 dacron ropes pulling up the antenna, that is why I am saying the antenna wire will be about 10' away from the tops of the masts. It is anticipated that the antenna will be fed by diy ladder line from one of the corners.

Any pointers or useful information is welcome.

tnx,

-bill

Hi Bill,

You are on the threshold of being able to do much more for slightly more effort.

Let's suppose you use wire with insulators to break them up (generally only advised as a must below tower mounted beams so that opportunistic resonances don't mess up directionality and tune).

Further, let's suppose all wires at the top have a good metal connection to the mast.

Further, let's suppose each of these wires is broken such that the first insulator(s) is more than 25 or 30 feet above ground (straight down, I am not measuring along the wire).

Nothing else matters beyond what you would then do for general construction.

I presume that all masts are driven into the ground (or at least are not insulated from ground); and that at each mast you could build a radial ground screen of eight to a dozen wires as broad as those first set of insulators are out from the mast (probably 20 to 30 feet each).

You then have the opportunity of developing four broadband vertical antennas (each with a gamma feed because of the grounded situation). There's a good chance they would operate on 80M without too much effort (you might push them to 160).

Most of the work is in the top connection, and the first set of insulators - beyond that no commitments are needed if you simply decide to walk away later. That is easy with little difference in the up front effort.

OK, I guess I have to do more thinking about this, even though my head is already totally spinning from the fact that there seems to be blatant discrepancies between expert opinions out there. I am new to this ng and have much to learn.

I am not sure who to believe at this point.

The book says "one common ground", AC safety AND RF, all one thing. This seems to be what is being advised here as well. This seems to be consistent with building codes. That is the "law", the politically correct physics, and what one needs to say in print or be liable, etc.

Then I turn around, and experienced hams are telling me the exact opposite, eg. not to tie the RF ground to the house AC safety ground. To tie the RF ground to the house safety ground rod means a much longer run and thus the potential problems of 1/4 wavelength resonance also mentioned here.

By the way, I am using an older Kenwood TS530S (until I get some experience and decide to invest in a more current rig). Are current rigs now always with three pronged polarized/grounded plugs? My unit here has a two prong non-polarized ac plug, just like the old audio tube amps I still use for hi-fi.

This whole "ground" thing and its history is quite mysterious, controversial, and confusing to say the least.

In 1953 when I was first a novice, I used a bizarre little homemade transmitter with one 117N7 tube which only plugged into one side of the house current!!!! and then used an earth ground and antenna. I am, in retrospect, amazed I am here and alive to tell the story.

Where is Tesla when we need him......

Just curious, if I were to take a light bulb and connect ONE terminal to the hot side of an ac house outlet and then connect the other terminal to a ground rod driven into the ground in the middle of a forest somewhere where trees fall without anyone there to hear them, will the light bulb light up?

bill (feeling a bit ungrounded at the moment.....)

Richard,

Interesting, even if a bit above my current point in the learning curve.

Generally, I am experimenting with antennas here, trying to find the junction between theoreticl concepts, and the physical realities of the real estate, building, and trees, etc. just all hams do, I am sure.

Antenna #1 is now up, it is an OCF stung between to trees, not bad.

But now I am moving on to #2 which is this proposed 160m full wave loop. I have collected a handful of these old masts (junk yards, the local dump etc.) nice material to have on hand.

Here is more detail of the proposed loop, so that I can better glean something constructive from your intriguing ideas.

Only one of the proposed masts will be resting on the ground out in the middle of the orchard. Three are attached to buildings (adding height) and one is attached to a sturdy wooden "telephone" pole (again adding height and a way of mounting). The idea of putting radials in the ground does not seem practical for most of these masts, however, your idea is intriguing none the less.

Since I have a bunch of masts to play with, and I am in the antenna experimental mode, and have rural real estate to play around in, I am wondering about the antenna you have suggested.

Maybe we are talking about the possibility of Antenna #3 here.

Am I to understand that a promising antenna (you call a broadband vertical) can be made from a single 50 foot telescoping tv metal mast, the base of which is at ground level, utililizing the guy wires as part of the antenna system, with a system of radials in the ground underneath? How would I best feed this antenna, and would it be worthwhile with just this single mast, and what advantages would such an antenna have over others that I might construct?

At this point, I have only made plans for various wire antennas. Do not have any verticals. The tower and beam are only a twinkle in my minds eye, and I have to visit that neighbor who has a 75 footer he is not using that he suggested might be for sale, but that is down the line a way. Meanwhile I am tree fishing here, and recycling masts when I can find them.

I have more or less concluded, that my nicest 50 foot telescoping tv mast, is not the way to go for a "beam" and rotator, even the small ones, the engineering of such a project seems to court a Laurel and Hardy kind

of fiasco in my imagination, at least until someone tells me that they did it and it was smooth sailing.....

which is to say, I do not yet have a plan for some kind of antenna which can be rotated....whatever its desing might be.....

man, there is so much to this antenna thing......it is what this is all about.....and I love it....

The basic confusion that arises is in the distinction between RF and
Mains ground. You can keep your RF ground rod (add some radials to it
to actually make it RF ground) as long as you tie it to the Mains
ground (usually in close proximity to the drop and meter). The
distance between THESE two points is immaterial RF wise as your RF
ground will insure little or no RF current travels to the Mains
ground. In THIS sense, they are separate.

If there is noise (RF) on the Mains, it may seek your RF ground
through this connection, but as long as you are not sharing it (you
are not using this lead to both connect your equipment AND connect the
two grounds) then there will be no problem.

You should have a lead from your equipment to the RF ground and THEN
to the Mains ground (two paths, one conductor) in that order:

MAINSGROUND-------------RFGROUND------------SHACK GOOD
MAINSGROUND----------SHACK-----------RFGROUND BAD

>plug, just like the old audio tube amps I still use for hi-fi.

Most rigs aren't AC powered at all - they require 13.6VDC that comes
from an AC powered DC supply. AC power is floating with a
Hot/Neutral. Neutral eventually finds ground but you are in jeopardy
of relying on that. Ground, the third wire, is a safety consideration
and is never expected to conduct current except as a consequence of
failure. Modern construction practices and code certainly mandates a
thick enough conductor, but not for the purpose of supporting power
needs.

This is also from an era when newspapers reported the passing of husbands or wives who, while washing the dishes, leaning on the stove, playing with the toaster, putting down the iron, turning off the mixer, or holding the refrigerator door.... leaned over to turn down the radio volume - classic across the heart scenario - classic results.

They were killed by "modern" engineering design techniques to reduce noise (caps across the mains to the metal frame). Let's see, is it suppose to plug in this way, or was it the oth.*#!!**#.....

I think this is starting to make sense, maybe. My RF ground rod which is directly under the station about 6' directly down, also ties to a series of additional rods about 10 feet apart in both directions from that first rod (I am thinking this is like a radial since the bare wire connecting them is also on the earth (?). Should I connect the furthest rod of this series to the house mains ground rod which is actually not that far away at that point? Would I be ok then?

Cross-posted to: alt.ham-radio.vhf-uhf,rec.radio.amateur.antenna,uk.radio.amateur

Lowe LAC1 new unused window clip aerial mount.
The last one I have (at the moment) being auctioned
for funds of East Cheshire Radio Group.

Please have a look at this auction -
http://cgi.ebay.co.uk/ws/eBayISAPI.dll?ViewItem&item=3091364426

ideal for the temporary aerial while on holiday !!

Thanks Martin

I may still be confused here, not really fuly comprehending the above illustration.

The mainsground comes to the shack anyway in the AC outlets powering the shack, being the third or ground terminal (although not really connecting to my Kenwood 530 which in this unique case only has a two prong AC plug and internal power suppy.

I think this ground thing has to do with the "routing" as you indicate, just as the mystery of ground loops in an old tube hi-fi amp where the correct star grounding is the way to get rid of hum. As long as my shack RF ground is a short direct route to the first ground rod of the series, I should be ok then tying the mains ground to a "later" point in the RF ground rod system. (?)

Hi Bill,

We will do this by stages.

We are going to maximize what you already have: mast material.

Grounded or ungrounded are immaterial - there are ways of getting RF
into either. If grounded, this may require a drop wire described
below (I was a little too enthusiastic about possibilities in the
first post).

The masts will be guyed. The trick here is to think in advance to be
able to support ANY mission, vertical OR horizontal antennas. BOTH
may be available at the same time.

The usual vertical of 50 feet may resonate at several places in HF,
but almost certainly not in the Ham bands - so we must expect some
form of matching along the way. For ungrounded masts this can be done
within a meter of ground so there is no going aloft to perform any
jobs. For grounded masts you may wish to have a conductive yard arm,
perhaps more accurately described not as a yard but as 18 inches,
dropping a wire to ground for a 160M or 80M Gamma feed, or as a folded
monopole.

Note, I suggest 160M or 80M operation for an obviously too short
vertical. This is where the guy wires come in handy. As described
previously, think of them as the skeleton of an umbrella (no fabric,
but ribs expanded out). With the use of insulators, this can be
achieved so that you can construct what is called a "capacitive top
hat." Such additions to verticals lower their resonance (but this
does not imply it makes them 50Ohms - that is a separate issue). You
want them to be resonant (so they will absorb and radiate power), but
you will need to match them further (no different that any wire
antenna for that matter). For 80M, this antenna will probably offer
20 to 30 Ohms (not bad, but not 50). For 160M, this antenna could
offer 5 to 20 Ohms (becoming difficult, but not undo-able), but in all
likelihood, it will also have reactance (the top hat will probably not

be big enough).

Now, why would you want another 160M antenna? The bad news is that horizontals in this band are abysmal performers even if you could get one up the minimum quarter wave (a long way from only 50 feet up). Verticals on the other hand use earth far more effectively for communication in this band (how many AM stations do you know of with horizontal antennas?). 80M sits on the borderline of earth characteristics where horizontals may do better, but this doesn't mean that verticals do poorer. Higher bands see earth differently, and verticals need height (lifted into the air) to compete; or they need to reside near a lake or the sea.

However, most of this discussion gets very far afield. The point is to plan ahead, construct top hats (they will mix easily with your loop project) and think about the gamma drop wires if the masts are grounded. This is very little investment and you have four opportunities (this then brings experimentation with phased, vertical arrays - each mast driven separately through delay lines).

Yesterday I heard somebody talking over micro vertical antenna's for HF.
Seems very similar to magnetic loop's but easyer to adjust, and a bigger
band coverage.

They where talking about an 60cm antenna for the 40m band.

To bad I couldn't reply ...

Does anybody knows something more about this antenna?

Wouldn't sticking my multi/ohmeter into the material at a couple of points tell me if it dielectric or not? I did that and it would seem that this black poly pipe is totally non-conductive. If it contained carbon it would be like a composition resistor and register something (no?).

Anyway I am working on another source of rigid 3/8" dia. UV/PVC which might work out better.

Richard,

tnx a bunch for this fb. I am going to digest it a bit while I go out and mow the weeds around the prospective antenna mast sites (in my usual effort to convert manual labor into my preferred fantasies). I do see your important point about anticipating future possibilites before these beasts are already committed in the air, I like that approach. You have also inspired me to re-examine some of those carelessly glossed over chapters in the various Antenna books here at the shack.

We will undoubtedly need to continue this qso a bit more for me to fully apply your ideas to the particularities here.

So, to understand something basic: What you are talking about is not necessarily interferring in any way with the 160m loop project, but rather to anticipate additional antenna experiments utilizing the poles (masts). If the vertical antenna ideas are later explored, would each mast be a separate antenna requiring its own coax feed line?

btw, my newbie's facination with the ladder line fed 160 loop has to do with its multi-band promise. To tell the truth, I have heard very little on 160m here. Seems like (at least with the new 80m OCF (up 30' ++ depending on which end) I am hearing alot on 20, 40, and 80 with this old Knwd 530. Sure beats the old tube Hallicrafters I was using only a few months ago when I started my process of catching up with 50 years inactivity....!

I might end up one of those hams that loves the old tube gear, but also uses the latest technology as well.....those fancy Icoms are kind of tempting....but what do I know....

Hi Bill,

The additional ground rods don't do much, RF-wise. You are far better
off with wire laid out radially on or just below the ground surface.
However, what you have is good.

>Should I connect the furthest rod of this series to the house mains ground rod which is

There are several variables here other than the conductivity of the primary metal. Again, what you're seeing is not "the difference between copper and aluminum" as initially stated, but a number of other factors -- diameter, length, coating, and alloy --, combined.

If the DC conductivity of two materials differs by a factor of two, their RF conductivity differs only by a factor of the square root of two, or about 1.4. This is because the skin depth is greater in the less conductive material, which partially offsets the conductivity difference. The relatively small difference in DC conductivity between pure copper and aluminum is further reduced by this effect, so you'll very seldom be able to see any difference.

Sounds like a dummy load, or one of the attachments for the comet UHV6
multiband hf antenna.

If they figured out a way to make it that small and actually work very well
I'd love to hear about that.

Hi Bill,

Look again at the illustration. Now think of noise originating in the Mains and traveling towards RF ground. That current, across impedance, produces noise voltage. In the "BAD" illustration, think of the left hand as hot, and the right side as cold. Just like at a setting of a potentiometer, noise voltage is injected INTO the SHACK if there are other paths to ground (there always are, you describe just exactly how it happens above).

Now, repeat the same problematic noise current in the "GOOD" illustration. It sinks right into RFGROUND and does not proceed on towards the SHACK.

You will of course have mixed grounds because this vale of tears we call reality demands that you power your SHACK from the Mains. And if it weren't that, it would be the 'puter, or the phone, or a battery charger for the drill (the list is endless and so common that we become blind to the obvious paths mixing noise into our life).

Most local noise is conductive. That is, it comes from the source and the sink residing on the same breaker in the panel. The source noise current injects itself into the sensitive sink side that is sharing the path. By using an extension cord, you can confirm this by powering the noise source off another outlet that goes to a different breaker. That noise that is not conductive is radiative. It arrives from the source through the air. This can be nipped in the bud by

using a transmission line choke at its entry (generally the feedpoint of the antenna).

Hi Bill,

Being conductive and being lossy are not the same thing. You may have
both situations, or one, or the other; however "not being conductive"
does not necessarily mean "not lossy." The microwave test is hardly
conclusive unless you notice it heat up. Other testing is more
sophisticated.

Get Congress to Take Action

Sign our online Petition and read below for more information:

http://www.votenader.org/get_involved/impeach.php

HEY DUDE WHERE'S MY BUDDY!!!???
COME BACK HOME MICHAEL!!!

Ok Michael, you've had your realpolitik fling with ex-General Wesley Clark. Your endorsed Presidential candidate in the Democratic Primaries has withdrawn. It is time for you to come home, to join your buddies and resume your only genuine role which is that of defiance and resistance. Compliance and assistance with the Democrats does not accord with your past, your character, your bold writings and, most memorably, your long corrosive assaults on the Party that betrayed the working classes and plunged our country into corporate globalization. Remember, Michael, you're the flinty man from Flint, Michigan. You've never forgotten your roots. The heady Hollywood, Manhattan scene with the celebrities and Academy Awards have never gotten to your head but rather have gotten into your deserving pockets. How we all recall your standing before one billion people in Los Angeles at the televised Academy Awards in 2003 and, breaking the customary cant of the awardees, throwing the gauntlet down to George W. Bush and his "fictitious" war mongering.

Now the War has become a quagmire, with both Republicans and Democrats complicit (check the votes in Congress). The Draft may be on the way. So what are you doing going on the Al Franken Show very nearly breaking down when Al Gore (he of the pro NAFTA/GATT, anti-worker, regime-change, Iraq-bombing, lethal sanctions on half a million children Administration) called and thought you were apologizing. You have nothing to apologize for, Michael. Gore has a lot to apologize for-blowing the election he won in Florida and the country as a whole and for blowing, with Bill Clinton, the many opportunities the rich-booming Nineties and the collapse of the Soviet Union gave this country to turn a peace dividend into a pro-worker, pro-environment, pro-consumer and anti-poverty resurgence.

Come back and join our Presidential campaign, Michael. Talk to those "Reagan Democrats"-those 35% of union members who still vote Republican and against their own interests-as only you can. Michael, if you go pumping for the Democratic Party this year, just what are you going to say to the unemployed steelworkers near Sparrows Point in Maryland? To

the megathousands of laid off textile and furniture workers in North and South Carolina? To the abandoned auto workers waiting and waiting near their empty factories that went to repressive countries? To the millions of blue-collar workers, who fought our wars, only to learn that the two parties won't fight for their company pensions and health insurance? Are you going to tell them how the Democratic Party pushed through the WTO, let their pensions erode or disappear, were too busy collecting checks from the corporate bosses to pay attention to the corporate crime wave that looted and drained trillions of dollars from millions of workers, their retirement and small investments? Will you tell them that the cowardly Democrats, who couldn't win the fewer elections they are now not losing without the labor vote, won't even mount a determined drive to repeal the notorious, union-blocking Taft Hartley Act?

How can you be free to be what you are, or to depress Bush's vote, to jolt into consciousness the moribund Democratic Party?

Hey Dude, join your real buddies! The ones you may be thinking about just don't fit either your message, your vision, or our website VoteNader.org.

Come back home Michael. The workers and the youth of America are looking for you.

Best regards,
Ralph Nader

P.S. Will you put this invitation on your website and see how your fans react to Michael Moore returning to the Nader 2004 presidential campaign? Patti Smith will reserve a big singing spot, for you, on the stage for the customary finale, PEOPLE HAVE THE POWER.

Wednesday April 14, 2004

Join the Call for an Impeachment Inquiry of Bush and Cheney
Help us Get Congress to Take Action

You can help the call for an impeachment inquiry of President Bush and Vice President Dick Cheney. Sign our online Petition.

http://www.votenader.org/get_involved/impeach.php

George W. Bush and Dick Cheney should be impeached for two reasons:

They led the United States into an illegal, unconstitutional war in Iraq.
They misled the Congress and the American people with five falsehoods that led to war.

All it takes is one Member of the House of Representatives to call for an Impeachment Inquiry to start the process to investigate the two grounds. If the House then votes by a simple majority for Articles of Impeachment, the Senate would then undertake a trial of the President and Vice President. They would only be convicted, and impeached, if two-thirds of the Senate agrees.

--

people's war in our country
continues to blaze defiantly, expanding, spreading its roots and preparing for newer and higher tasks, guided always by Marxism-Leninism-Maoism, battling for the emancipation of our people for the purpose of and at the service of the world revolution. Thus we are contributing and will contribute to the tasks of the RIM, more and more willing and able to aid in every possible way our glorious common cause: the emancipation of the proletariat and communism prevailing though out the earth.

"Comrades, the Communist Party of Peru is part of the Revolutionary Internationalist Movement and feels honored to be so, honored to serve in such a far-reaching and historic vanguard battle, as well as to have the comrades in arms found in our Movement's ranks; and furthermore, the Party feels fortified and augmented by the repeated expressions of support, of proletarian internationalism, which it receives from the very outstanding fraternal communist parties and organizations, and very especially from the Committee of the Revolutionary Internationalist Movement to which we extend our revolutionary gratitude for its constant encouragement and support. All this, comrades, increases our proletarian internationalist responsibility and our unshakeable commitment to the world revolution and its concrete form today, the Revolutionary Internationalist Movement."

NION: ANSWERs Needed

Is NION's financial relationship with IFCO some innocuous charitable funding arrangement? > The Hi-Q is 1" diameter powder-coated aluminum 3' long.

A 2" diameter bare copper rod or cylinder at 14MHz, 3' long, should
have an RF resistance about 6 milliohms. The worst aluminum alloy
you're likely to see should be about 12 milliohms; 24 for the 1"
diameter. What am I missing here? How does that translate to a
change from 9 ohms to 20 ohms to 30 ohms at the feedpoint? If the
cause is resistance heating of the copper or aluminum tube, what's
doing the impedance transformation, and how is it so efficient? That
much loss should result in measurable temperature rise in the tube (or
wherever the loss is), at 100-W power levels.

Or perhaps my image of what you're measuring is all out of whack.
Same loading coil in each case? I'd kind of expect the loading coil
to be the main loss mechanism, if all the connections are tight.

Puzzled and seeking enlightenment,
Tom

Ohhhhh! I get it now. Its like why some kitchenware is ok for the microwave and some not. The RF might be heating my spacers and if the spacers are the wrong stuff, we have a melt down! Darn....why did all those neat industries making cool things out of glass and ceramic dry up and disappear.....

with the collectible price of simple glass antenna strain insulators you would think some industry would fire it up again, and while they are at it they could make some of them out of purple glass and the collectors would go nuts unleashing all kinds of cash on them. How hard is it to make things out of glass?

ps. has anyone actually heard of a diy ladder line having a spacer melt down while running power? no reason why it couldn't happen....

Now that I understand, I will at least put my prospective spacers through the microwave test....

Hi Bill,

This has never been reported here. Instead, it is noted by the
characteristic Z of the line being lower than computed. Such
measurements (of the characteristic Z) can be performed through a few
simple but still time consuming tests.

Thanks for all the excellent commentary guys!

My reason for the question was not really looking for a major improvement in the operation of the antenna, but more longetivity.

I'm getting close to retirement and have moved to a new state. Whatever I put up, I want it to stay up and keep looking nice for about 20 years or longer.

I lived in my last home for over 20 years, my backyard was almost solid copper from all the radials I had run over the years, plus when I first moved there, I did the entire backyard in 2x4 welded wire fabric, a layer of straw and some grass seed, then another layer of 2x4 welded wire fabric running the other way, then eventually sod over that. The last antenna I put up, a Butternut I used 3,500 feet of wire to make the radials and tied them to the welded wire fabric.

I have set up an area at the top of a hill, am in the process of grading this area to flat, and hopefully within a couple of months have everything up except the antennas.

I have cheap access to a plating company who will plate everything to keep it from corroding. When I checked into the price of gold plating, it was only a couple of bucks more than stainless silver or stainless brass and I was just thinking perhaps the gold would last longer and perhaps even work better.

I have 1,225 sq. ft. of small link aluminum chain link fencing that is going to be buried as the start of my ground system in this graded area.

I am also having a 62 foot fiberglass utility pole (50 feet after installation) installed at the corner of the house, this will hold my VHF/UHF antenna's and the my HF Inverted Vees, plus be the center of two dipoles, etc. Up near the antenna farm there will be another 30 foot fiberglass utility pole (after installation), which will be horizontal with the 50 foot pole at the house.

I'm just trying to get everything planned out on paper before I do anything as it's easier to erase a pencil line than redo an antenna farm after the fact.

In effect, I'm going to duplicate as closely as possible what I had in St. Loo and hopefully add a few more, since I now have the space.

Hi Gary,

Ships at sea, for millennia, have used bronze for durability. Talk about an aggressive environment. One of my buddy's told about his experience at the Naval Research Lab where a scientist offered a cube of solid stainless steel for testing. They dumped it into sea water and dissolved it.

Hi Jim,

What about them indeed? If they don't meet the requirements of bright untarnished metal, then they need pressure mating (all the good ones I know specify this - but deeply embedded within their core manufacturing specs) e.g. Amp RF connectors:
"Insufficient contact force will give rise to metal to oxide junctions. The classic rectifiers were metal oxide by composition.

"The applied mounting force is concentrated in the surface area of the protrusion which, on engagement with the panel, punctures the existing oxide layer to give a metal-to-metal, gas-tight junction."

The gold plating, presumably, precludes giving rise to oxidation products; however, pressure then becomes an issue of mating surface area (Ohms). Every precision contact used for Resistance and Voltage standards (in the old days) were tapered brass plugs that could be wedged into the jack with a twist (pressure). They knew about gold then too, but brass served admirably.

Why is this vintage so sought after?

Aren't there as good units available today that include all the current bands?

Any recommendation for linears in the same power realm which are comparable in reliability and price? Also, how do Solid State amps compare to Tube amps?

Is this true for all antenna designs? Is this choke various depending on other characteristics of antenna and feedline.

For example, in my anticipated 160m full wave loop which I plan to feed with diy ladder line to a Johnson Matchbox (250w), is there a specific recommendation for such a choke? Can I simply make what I need with a few windings of something around another round something and than wrapp it in rubber tape etc. Is this something I can incorporate into the hardware system at the antenna feedpoint where I will be attaching the two ends of my loop to the ladder line?

Hi Bill,

Each formulation seems to be distinct, but offhand I don't recall
which is which. To broaden your experience with this forum, visit:
http://groups.google.com/groups?oi=djq&as_ugroup=rec.radio.amateur.antenna
and checkout their advanced search page. Use "PVC" and "Loss" as
keywords in the search. The topic is not so novel as to be sparsely
represented in the archive.

Hi Bill,

Feedline chokes are principally designed for the nature of coax which
is unbalanced by design. Ladder line is presumably balanced and thus
resists noise pickup of local origin. However, the balance is
strictly a matter of its load, and if either end of the line meets an
unbalance, the whole system is off balance and noise can intrude
through what is called "the common mode." As such, balance is a very
local thing that only you can determine through performance.

I imagine that a loop would be harder to unbalance; but dipoles,
especially low ones, are very susceptible.

This item is one of the 'collector radios'. Just as some older cars are
more desirable to restore than others. The Heathkit will work just as well
or beter than the Collins but does not have the collector value. Maybe
there were more Heathkits made but they are around $ 300 for the 1 kw modle
and the Collins are twice that or more.

> Any designs for a small antenna to work on 160M? My garden is approx 40ft
x
> 17ft.
==========

Hi, M3,

The following set-up will work okay. Been there, done that. Height is the critical dimension. It will be about 2 S-units worse than ideal.

Inverted-L antenna. Vertical section = 40 feet. Put a pole on house chimney to increase height. Horizontal section 40 feet. You can extend length at far end by making it an Inverted-U.

A sytem of ground radials is essential. 8, 12, 16 shallow-buried radial wires at least 25 or 30 feet long in ordinary, damp garden soil. Important - connect the domestic plumbing pipes and incoming water main to the ground radial system.

A tuner is essential. The average commercial tuner will NOT cope. You will need a home brew tuner. Wind some tapped coils on toilet roll tubes using 20 or 22 gauge wire. Inductance values up to 100 uH. See program SOLNOID3.

Tuning capacitor = 500 pF maximum, 750 volts working, not particularly wide spaced plates. A LARGE old-fashioned receiving-type capacitor would be OK. Also obtain a few fixed-value, mica capacitors. Be prepared to experiment with tuning capacitor and coil values.

If you like playing with a few numbers, download in a few seconds program ENDFEED from website below and run immediately. This program computes performance and also provides values of T-match and L-match components for given antenna wire dimensions.

160 meters, 50 miles groundwave in daylight with 100 watts. Transatlantic on CW, if you try hard, on long, very quiet, winter nights.

It will be also be usable at high efficiency on higher frequency bands. For practical purposes, taking one band with another, it will be omni-directional.

Get program ENDFEED from -

Well Tom, I'm just looking to explain the data: I'm puzzled as well.
Same truck, Durango with a ball mount right rear.
Same MFJ analyzer. Same very short coax from inside the truck.
Everything grounded with 2" copper strap.
Same 14.300 MHz; Same whip. The measurements repeat reliably.
Three motor-tuned antennas, Nott, Tarheel, Hi-Q.
Three different impedances at resonance (ie purely resistive load.)
9, 20 and 30 ohms. Now I can see the radiation resistance being slightly higher with the Tarheel, it's a foot longer, but that hardly explains a factor of two. So it must be the loss resistance. Part of the difference is the base tube, and the copper/aluminum/diameter issue obeys the appropriate scaling laws. (BTW I think the Hi-Q is 1.5" diameter, but I'm not sure and I am not at the ranch where the antenna is stored.)
When I adjust the tap on the transformer to give a 50 ohm load to the MFJ for each antenna, the Nott gives the greatest near-field signal strength.
Perhaps a further investigation of the remaining sources of resistance is in order. The Hi-Q should have the least leakage, it's a beautiful piece of work. The Tarheel appears to be built of better materials than the Nott. (Lexan vs PVC for example.) Go down to 80 meters and they're all 10 ohms; coil losses clearly dominate there where radiation resistance is tiny.

I think a complete solution to Maxwell's Equations would be helpful, but I'm busy at the moment.

For all I know the paint or powder coating on the aluminum antennas is the real culprit.
The Nott's just bare copper.
What is the radiation resistance of an 8 foot whip antenna resonant in a 16.5 foot world?
Just a bit less than 10 ohms, right?
Maybe the comparison should be to BARE aluminum.
Just my morning thought on a puzzle I've been looking at for several months.

I took a look at it and it's not 100% clear to me from the sketch in your website how your loaded vee is actually laid out, half of it seems to be "missing". Is the "missing half" another complete leg attached to the other side of the balun? In other words is the end-to-end overall "wingspan" 80+ feet? If yes how could it fit in the M3's 40 foot back yard? Or am I missing something very fundamental??

Hi Dan.

I took the liberty of forwarding the message to
rec.radio.amateur.antenna. It is a better group for this subject.

Your question is a little broad. I'm not sure of the application, base
or mobile, or if you would like a multiband or what.

If you want a good general purpose antenna, there are multiband 2m/70cm
ones out there. Single band antennas work well also. I've made a ground
plane for the house, and the mobile antennas use the car body for the
ground plane, although I've heard some discussion to the contrary. A
number of people like J-pole antennas, I've just built one for 2 meters,
and am evaluating it now.

If you want more "gain", you might look into one of the multi-element
antennas. These are a good deal more expensive, and need a rotator, as
the gain in one direction is offset by a null in the opposite direction.

But so much depends on what you want to do. If repeater operations are
your main interest on the higher frequencies, then the ground
plane/jpole approach is better IMO, unless you are on a fringe area and
need the gain just to hit the repeater.

On six meters, there are a number of options, from dipole to the
multiple element antennas also. The same ideas apply.

Hope this helps, but if you like, you can give us a few more details.

Save your money. An Isotron for 160m is simply a very bad idea.
The best idea so far is a vertical, as tall as you can make it,
with a radial system as extensive as you can make it, with a
top hat as big as you can make it, matched at the base of the
antenna.

Hi Brian

There are two legs, only one is shown as the other is identical to it.

The closer you bring the ends the more directional the antenna becomes. I had my legs 80 feet apart on one system and only 25 feet apart on another system, both worked equally well, except the one with the smaller spread was considerably more directional.

In my response I had asked if the poster could eke out another 6 to 8 feet, making that 17 feet dimension possibly 23 to 25 feet wide. Because at under 20 feet of spread, it begins to loose some functionality and noise levels increase exponentially. At least where mine was installed that is.

I had tried all kinds of antennas for 160 in my small backyard and this one worked the best for me in my situation. Many others have used it, most with great success, but in some locations it worked worse than other designs they were using.

When I moved the legs from the northern facing backyard to the southern facing front yard, the antenna did not work very well at all. Probably because of the many obstructions around it when situated in that direction.

It's cheap, easy to assemble and try, if it doesn't work, you still have your two 130 feet sections of wire to try something else.

I used an isotron 160 antenna for a short time. Working local stations
it worked great but I was never able to work any DX.

My guess is that he's interested in a mobile antenna due to mentioning the mag-mount. Diamond has a 6/2/440 mobile antenna available in either UHF or NMO mount; it can be connected to just about any type of vehicle mount as long as you go UHF to UHF or NMO to NMO. The radio mentioned is a handheld with an SMA mount, a means of connecting the PL259 to the SMA is needed. I'd recommend one of the newer adapter cables as using a direct 239 to SMA adapter will put notably more stress on the SMA connector on the radio and that's inviting problems.

Anyone remember "beldfoil" aluminum sheilded cables?
It was sold in the 70's as a replacement for copper shielding.
After a few months exposure to salt air, the aluminum turned into white
powder, leaving only the drain wire as a sheild. Not very effective.
I think they've given up on that, and gone back to copper, though I have
seen copper shield used along with the aluminum-mylar material.

986. Re: Micro Vertical

The secret to the MicroVert and other "amazing" short verticals is the choked quarter-wavelength feedline acting as the primary radiator -- contrary to claims that it defies physics and doesn't radiate. The short vertical element and its accompanying accouterments are contributing very little to radiation but a lot to imedpance balancing -- the need for which is caused by the short element. It would actually perform better as a low-angle DX antenna if the "counterpoise" were made vertical and the short loaded element made horizontal.

Hi Richard,

Thanks for the link to the archives, I will check it out.

I imagine there a few hams who want to make their own ladder line these days. Other than finding some vintage ceramic spacers (rare) what are they using?

Apparently paraffin soaked dowels are not without some shortcomings. I think there is at least one ham who has a cottage industry selling his homemade version ladder-line which, from what I can gather, utilizes the black poly piping that I mentioned earlier.

I think I came across at least one ham who has used the grey UV/PVC pipe which he slices (saws) lengthwise and then drills holes and/or notches etc. This seems a bit labor intensive if one wants to make any quantity, but maybe not as much as I think.

If the UV/PVC pipe is a good solution, I might be able to track down a source of 3/8" UV/PVC pipe which I would not slice up, but just cut into 6" lengths and then devise a fastening system on either end for the wire.

Bill

First thought is that it would heat up and detune itself. But this would only be a problem on transmission and if the tube holding the mecury was very thin. Conductivity of mercury is not so great compared to more traditionally used metals but this should not be significant compared to the radiation resistance of most antennas.

Dear Dave,

It is simpler to do the earthing at the point where the coax is coming
as close to the earth as it gets.

You may find it helpful to build a "ground frame", which is a metal
framework having bulkhead UHF connectors in a metal plate, which is
then well earthed. The coax lines from the antennas come to this plate
and then proceed into the shack from the other side. You can place as
many deep ground rods as you like around that frame and connected to
that frame - the more the better.

From: zeno <zeno@sonic.net>
Message-ID: <4082C483.E1E7998D@sonic.net>
Source record: 96392

Hi Richard,

I think at least one of the metal masts I will be using to hang the 160m loop might lend itself to the vertical antenna you suggest. It is the one that is a full 50' in height, and will be out in the middle of the orchard where ground radials can be installed easily. Unfortunately this particular mast is the one farthest away from the shack, approx. 500 feet.

Questions:

1. For reference purposes, what is the exact description (name) of this vertical? Any recommendations for information in print about this concept?

2. What band, or bands, would it be good for? (Assuming the guy wires are generally in the position of effectivenes as guy wires.)

3. Would it be monoband, tuned to an exact f, or possibly multiband?

4. Where would one attach the feed line and would a run of 500' to the shack still be worth the effort?

5. If I understand, the antenna is comprised of the mast itself (with telescoping sections securely and electrically bonded to each other) plus the "extension" of calculated lengths of the four guy wires, utilizing insulators at precise points before being attached to ground anchors.

6. How would the mast be mounted to the ground? Should it ideally be isolated from ground or contiguous with the ground? Theortically I could build a short wooden platform or something.

7. Other than the mast itself, the four guy wires, and some kind of system of radials in the ground, are there any other elements to this antenna that I should know about or be thinking about?

Bill

Richard,

I just remembered, there will be three tiers of guy wires (four wires at each level), one set at the top, one set ten feet down from that, another ten feet down from that,etc.. Can all of these guy wires be part of the antenna system? Like you mentioned, kind of a "umbrella skeleton". It might be tricky to make sure that the guy wires both bond to the circular ring around the mast which the wires attach to, and to make sure that this metal ring also bonds well to the mast, I will have to think about a good technique here. I guess I could carefully weld them in place (normally they are tightly fitted to the pole, but can still slide up or down), I am sure you have seen these old tv telescoping masts, they seem fairly standard.

Hi Jimmy,

There are so many things wrong with this sentiment....

For one, this "tube of mercury" (that everyone takes for granted) to
be "tuned" by temperature would have an exceedingly small capillary
(my lab models are easily less than 1mm). Second, constructions of
wavelengths longer than for 2M are laughable (but then, so is the
entire concept). You could never support the column within it as it
would draw a vacuum in its collapse under the influence of gravity
(AKA barometer). Try to counter that with a thinner capillary
(anyone see where this is going in comparison to radiation
resistance?) and almost any heat expansion will rift the enclosure.

When do we get to depleted uranium elements that pre-ionize the ï¿½ther
around them for "matching?" Will it escape the notice of many that we
would have to then abide by exposure rules from both the FCC and the
Nuclear Regulatory Agency? Or even the NIH?

Hi Gary,

Look for what is called "white bronze." Such is the premium connector base metal that is then plated with Gold. The reason for this is to reduce IM products (the Bronze has a lower electrochemical interface).

Why doesn't someone write a book on radiating feedlines? They'd be a
heck of a lot easier to put up than antennas :-)

Hi Bill,

The current is densest at the feed point for a quarterwave vertical.
Invest copper density in the first eighth wavelength with fewer
radials migrating out beyond there, and so on for as much as you can
tolerate.

The classic FCC grounds run from 112 to 120 quarterwave lengths to
give something like 95% shielding from ground (the point of radials).
Scaling does not follow a strict law of proportionality as 60 would be
85% effective. The proportion is more log based than arithmetic such
that a dozen (roughly a tenth of the FCC standard) would be at least
50% effective. Now, such pencil-whipping is based on abstractions
drawn from full quarterwave radials under a full quarterwave radiator
(classic field work for AM stations). As such, there are a lot of
variables to consider, and yet a dozen, eighthwave long would be a
solid RF ground.

However, few of us have properties that long/wide (without things in
the way) when trying to get into the 160M band game. So ultimately
you do what you can and don't gloat to those who know better. On the
flip side, 160M RF penetration into the ground is substantial and the
traditional ground rods do offer some advantage, and as Reggie offers,
so does the water service - find pipes.

Another myth exploded is when you hear DXers crow about horizontals
have no need of ground systems - they obviously have enough "gain" to
discard the 1 or more dB advantage in a ground screen below their
prima donna antenna.

RF ground serves many functions:
1. A reference to tune against (stability, a sink - what you seek);
2. A shield to reduce ground loss (more gain);
3. A reflector to enhance low propagation angles (more gain).

Please note that number 3 is offered for verticals only, at distances
of many wavelengths away - such is the advantage of shore placed
antennas. As such, "ground" is a misnomer (swamp, lake, ocean, or sea

serves instead) - and ignore the babble about the "conductivity" of these being so much better. It is the drastic mismatch between the ï¿½ther and the body of water that does the DX charm, conductivity is in the toilet.

Does anyone recall seeing an article for constructing a return loss bridge
in RF Design in late 80s or early 90s? I'd like to see if I can get a
scan, I've been bitten by the RLB bug.
tnx
Hank WD5JFR

A 1/2WL dipole is an open-circuit radiating feedline
complete with reflections. :-) From Balanis: "The current
and voltage distributions on open-ended wire antennas are
similar to the standing wave patterns on open-ended
transmission lines." Wasn't the original Gap antenna
simply a leaky transmission line?

Folded Triangular Unipole is 45 feet tall and rated from 3 to 10.5 MHz

NORD 30 feet tall and rated from 2 to 4 MHz;

Folded NOL Unipole is 0.124 wavelength tall;

Type UG is 0.048 wavelength tall.

>
>3. Would it be monoband, tuned to an exact f, or possibly multiband?

Depends on antenna type and number of guy wires. The devil is in the
details as the saying goes.

>4. Where would one attach the feed line and would a run of 500' to the
>shack still be worth the effort?

At the base. Run an exciter to a remote amp. That is, put your loss
into the cheapest signal to boost. Move the shack ;-)

>5. If I understand, the antenna is comprised of the mast itself (with
>telescoping sections securely and electrically bonded to each other) plus
>the "extension" of calculated lengths of the four guy wires, utilizing

Exactimundo.

>6. How would the mast be mounted to the ground? Should it ideally be
>isolated from ground or contiguous with the ground? Theortically I could
>build a short wooden platform or something.

Folded Unipoles (which are wide band within the band of interest and
some bands are very wide) are fed with their base at ground potential
(add radials here). The feed point is through a cap, up the drop
wire. that is descending from the conductive (half) yard arm.

The other types are fed in series (the base insulated from ground).
Comparisons should be studied. If building an insulated base is no
problem, shorting it to ground becomes an easy option.

>7. Other than the mast itself, the four guy wires, and some kind of
>system of radials in the ground, are there any other elements to this
>antenna that I should know about or be thinking about?

Don't forget the drop wire. Search the web for Folded Unipoles
(verticals) for illustrations to make this clearer. There is also a
series cap to tune it. It is basically a very big gamma match.

By varying the diameter of the drop wire to the mast diameter, you get
transformer action that boosts or lowers the feedpoint R. As most of
these are very short antennas with very low radiation resistance, the
wire diameter to mast diameter ratio often boosts that value to 50
Ohms without too much problem.

WARNING, this boost does not raise efficiency! That remains a
function of the radiation resistance compared to structure Ohmic loss
and ground loss. The feed point R is simply a boosting of BOTH the
radiation resistance AND those loss Rs too.

This goes back to my original question, should I use rope or wire for the guys on these masts. If I use the dacron rope I would use pulleys so i can later change out the rope if need be without taking down the masts. My concern with using wire as guys (as was usually done with old tv masts on roofs) was that all these lengths of wire in the proximity might in some way adversely effect my 160m loop.

Using wire guys would be easier. Aside from all this additional complication of anticipating some kind of future vertical antenna system I barely understand at this point, is it definitely ok to use wire as guys? I might just use wire guys, not broken up with insulators, not worrying about these future antenna possibilities. These masts are simply too far away from the shack, but I need to guy them just to put them up.

When using metal masts for wire antennas, what is the standard practice for guying these masts?

I will not really understand this antenna until I can see a simple picture of it somewhere, and, since I am a beginner, would need to know what purposes such an antenna might serve me at this point, eg. is there a particular band or a particular advantage that I cannot get elsewhere with my other more common antenna systems. I am at a point where I am simply looking for possible worthwhile antennas I can construct hoping that one or two might prove effective.

You did mention something about the advantages of vertical over horizontal and I was not sure which band you were referring to. At this point I have not considered any vertical antennas, but am open to verticals, if not the folded unipole you are discussing, maybe some other kind of vertical. At this point I don't know anything about verticals really other than the hassel of putting in radials. I like the idea of a mast being an antenna and the guy wires being part of the antenna, but what I need is a child's picture book illustration of such an antenna and why such an antenna would be the bees knees for me.

Here is what I currently (and practically) understand about the antenna you are discussing. It is a vertical folded dipole of some kind in which the 50' mast is one leg, another drop wire from the top is the other half (which I assume is fed somewhere in the middle of this drop wire by hooking up coax feed line). In addition to this folded dipole (vertically oriented) and with one leg (the mast) much greater diamter than the other half (drop wire), it has a bunch of guy wires attached to the mast at various points which somehow add something to the antenna, the guy wires need to be some special length. There needs to be an elaborate radial system underneath threaded through the orchard with weeds growing on top of them and not shallow enough to get caught in the mower. To even use this antenna, on whatever mysterious band it is good for, I would have to make special electronic accomodations to deal with the loss resulting from the feedline being greater than 500 feet to the shack (or move the shack closer to the antenna), eventually this long feedline would have to be in conduit and buried.

I think that it would be easier just to put up another mast, closer to the shack, just for the purpose of exploring this antenna, rather than bend over backwards to make use of a mast out in the field just because it is there. These old telescoping tv masts are plentiful at the county dump, I will keep collecting them. It is conceivable I could put one up with a feedline less than 200 feet to the shack, that shouldn't be any problem with loss, no?

But I still need to know, or be reminded, in the simplest of terms, why I want such an antenna, and what special advantages it might have on what bands I might eventually be excited about.

Hi Zeno, Read back thru this thread, there have been all sorts of suggestions. You can use cut up plastic coathangers, plexiglass, PVC, cut-up vinyl chopping boards ect., for spacers. The spacing can be 1"-6". The wire can be #14 insulated-#20 insulated or uninsulated. Saw a number of suggestions to get it in the house.
My suggestion is to pick out a method and materials that you like, and try it out. You will probably be pleased with the results. I like all my ladder (open wire) line

Ah! Thanks a lot! Actually 2 Meters is really the ONLY one I'm wanting to be using. I have a new Icom T90A, and just want a nice car antenna for talking on 2 meters. It's an HT. I have an actual Icom V8000 rig, but that's for indoors. (Got a beautiful Diamond X-50 for that, and I get repeaters all over the place here in the sierra foothills. Though I have to get to work on my coax, which is damaged, but ... Got the new coax and connectors, and will be dealing with that after I move to Indianapolis.)

For now, I want to operate with a reasonable degree of effectiveness from inside my vehicle with my HT. It's a fine, fine HT. My biggest concern is 2 meters, and whether or not it comes with the coax I'll need to put on my car. Again, I am VERY new to this hobby, having only gone on the air a dozen times (since moving has taken all of my energies) and I want something to use in the car. I have a mag mount, but it has the bayonet style connector. I'll need an adapter, but I ALSO want to get a good antenna. My radio only puts out 5 watts max.

I wouldn't mind being able to test out some 6M, but 2M is most important for me. Thanks so much for your help and interest in helping.

Hi Dan,

So it is desirable because it is great to have Collins quality and reliability, and the compromise of its not having some of the current bands is forgiveable in light of its collectibility.

Vintage has a certain "bargain" appeal because you get "yesterdays" high quality (USA) without the very high cost of today's quality units. I just wondered how people felt about the apparent compromises in band versitility, and the slightly lower power.

I just found several hundered feet of used #10 solid copper, insulated wire, it was pulled out of my well (submersible 240V pump) a few years ago. Any reason, aside from weight, not to use this #10 wire for constructing diy ladder-line? I understand the bigger the wire the less the loss (what little there is with ladder-line), also I understand that solid core copper will stay straighter and maintain the spacing better than braided. The insulation is kind of thick and rubbery (it went down to the well submersible), would it be better to cut off the insulation or just leave it? If cut off do I need to clean it up further or just leave the residue on the wire? Since this is three wires braded together I would have to do some major straigtening first. Maybe this is just a bit too heavy, now that I think of it, there is alot of copper there. Any motivating advantages???

Hi Bill,

I have a 40 foot military vertical mast that can be guyed at 4
intervals. Comes with stakes, rope (nylon), hardware, and a 5 pound
sledge hammer and it all fits into a 5 foot duffel bag.

As for bonding the lower guys (if they were wire), that would not be
par for the course. The top loading is only described at the top.
This is not to say such "linear loading" wouldn't be useful, but the
topic becomes more elaborate.

Hi Bill,

Still a very good question. As I put pulleys up many trees (pulleys
at the bottom to for a continuous loop, flag pole style), your point
is well taken.

>My
>concern with using wire as guys (as was usually done with old tv masts on

For a loop, it depends on how you drive it and if it is square. This
is the story of the origin of the quad in Quito Ecuador at HCJB. If
you corner feed it, then each corner exhibits hi-tension and becomes a
source for corona. If you center feed it, you rotate those hi-tension
points into the centers of the other sides. Less sharp bend, less
corona prospects.

I would imagine wire supports in the vicinity of a corona bend would
spell trouble.

Not only do I use non-conductive rope/string for my guy "wires",
I use non-conductive supports, wood/fiberglas. Works for me.

Anyone just use lengths of copper pipe or tubing? You might only need a tiny spacer every 5 feet or so. Was that you or someone else who made the ladder line out of tubing shaped like a sine wave.... hi hi

seriously, though, if one needed a section of ladder line to really stay put (say a section which gets nervously close to other naughty metal things or wire, why couldn't you fabricate just that section out of copper tubing and then go the rest of the way with wire? Are there impedance issues when changing the wire thickness along the way?

Okay, now we have something to work with. I'm using a 5/8th wave antenna on my car. It works pretty well. I'd suggest one of those. The brand is MFJ. Some don't like them, but it has performed well for over 3 years now. It has a small bottom loading coil. If you can spare the height, a full length version should perform a bit better.

Most come with coax.

Then you have to deal with mounting. I use a mag mount, and can run the cable between the doors of my Cherokee and it looks good. If that doesn't work for you, you can possibly run the cable down the back and into the trunk, then back up.

You can also use a trunk lip mount and do the same.

If you are really brave, you can body mount the antenna, but that is quite a project.

I don't recommend glass mount antennas for 2 meters.

After mounting the antenna, get a bnc or sma adapter, according to your needs, give the swr a check, and there you go. The big thing to look out for on installations is to avoid crimping the coax between doors, trunk lid, etc. That can create a swore problem.

I used a HT in the car for quite a while. (FT-50) Worked just fine. You should be happy with it. With a decent antenna and 5 watts, it is impressive how well it works.

Hi Richard,

Interesting about the loop configurtion. My propose loop was at first going to be square, then after scouting the actual route around the real estate here, it became more of a trapazoid with the feed (diy ladder line) in the corner of the shortest side. Upon more precise measurement of the actual perimeter inscribed by the four masts, it was discovered that said perimeter was actuall about 50' in excess of 540' loop length. Now I am planning to add the 5th mast (the one in the middle of the orchard discussed earlier) which will both put a little new "corner" in the longest side and also add renewed elevation (50') to an otherwise sagging 180' continuous run, this 5th mast will be used to pull out (via pulleys and dacron line) some of that 50' excess to the 540' loop length.

So basically we are talking a squarish 160m full wave loop, fed at a corner. Since I may not actually hitch-hike the vertical unipole we discussed on any of these masts (having plenty of other options on my 7 acre spread as well as other masts) maybe I will just make life simple and use the dacron and pulleys for the system of guys. But this does still leave the metal mast in the proximity of these corners, so the question is: how much more of a problem (corona etc.) is adding metal wire guys to an already existing metal mast. My simplistic intuition is, the more wire at more angles in the vacinity cannot help the situation. So unless I hear otherwise, I guess I will plan to use the dacron for the guys on all masts.

Speaking of trees and pulleys. I just had my first experience putting up an 80m OCF between two trees 140' apart. I used a sling shot method. When the antenna was hoisted, the rope perch at the top dropped down and although the antenna does work (especially better than my previous random end fed long wire), I do have to do it over again to get it as high as the trees are capable of. After a little wind storm, it dropped down further. Trees are a challenge. I am hoping to meet the local ham-archer who, rumor has it, can shoot an arrow exactly where you want it with exactly the right amount of momentum. He will definitely be necessary to get a line 175' up my Eucalytus tree in the back section of the property where I was fantasizing a 160 OCF and an alternate "getaway" shack.

I may just end up with little alternate ham shacks anywhere where I can put up a good antenna here. This will be another definition of "mobile" or "portable"......

Bill

Hi Cecil,

Tell me more about your wood/fiberglass supports. How do you make a 40-50' mast out of this material? Is this a type of nautical craftsmanship? Do you feel that the metal masts are inviting potential problems or do you think my proposed loop might be in the ballpark of ok to good with the metal masts at the corners? The actual loop wire may be ten feet away (via ropes) from the top of the masts.

You want a mag-mount 5/8wave Larsen... it's a
nice 1/4wave on 6m, too. Get the Larsen mag
mount, too... your present mag-mount (probably
BNC, with a duck on it) is insufficient... BNC
connectors are not rated for outdoor exposure.
Just run the coax in the passenger side, via the
rear door's front edge, down the center post, and
under the rocker panel to the dash.

That's interesting, so you find wire whose OD is just right for the ID of the tubing and that makes a good enough connection and is adjustable. How much adjustment were you after, inches or feet?

I use 2x4s to get to 30' and then 1.5" fiberglass tubing for the other 20'.
If cost is no object, the entire support could be fiberglass. I got mine
from: http://www.ryanherco.com in Houston. Fiberglass pipe is really
handy for a number of applications (including Escrima Sticks :-)

I just relied on skin effect to effect the proper conductive function. RF
won't flow into the inside of the tubing if it has any other "choice". :-)

The thing was adjustable from 20 feet to 35 feet in order to make a G5RV
truly a fully functional all-HF-band antenna. It really did work nearly
perfectly and could be automated using something like a screwdriver motor.

>the guys on all masts.

Goferit.

The answer to proximity (seeing you have more perimeter than you need)
is to simply keep the corner off, away from the mast about 10 or 20
feet. In other words, you put the masts at corners that are well
outside the bends of the loop. Thus you are suspending the loop bends
with dacron line (through the pulley) such that THOSE bends are well
inside the box described by the mast co-ordinates. (Think box inside
a box co-ordinate system. The exterior box corners, the masts,
support the interior box corners, the antenna.)
View with fixed font:

```
M--------------------M
|\ /|
| \ / |
| ................. |
| . . |
| . . |
| . . |
| . . |
| . . |
| . . |
| ................. |
| / \ |
|/ \|
M--------------------M
```

where
M is mast
--- is a ghost line
/ or \ is dacron going to antenna wire
... is antenna wire

You have the flexibility to put acreage to work for you, don't try
passing the bends through AT the mast itself.

Ah, finally, someone who knows what the conductivity of silver oxide is. Although I believe silver sulfide is much more common than oxide, I've been able to find the conductivity of the sulfide but not the oxides. Just what are the conductivities of the silver oxides (AgO and Ag2O)? Which are we most likely to find on the outsides of wires? Are they really more common than the sulfide?

Zeno, all of your suggestions would increase the weight of the
feedline, and possibly stretch the antenna. FYI, a 500-ft. spool of
#14 or #12 insulated, stranded copper wire from Lowe's Home
Improvement (or Home Depot) runs about $15.00

An interesting and eventually amusing link on silover sulfide

http://www.eecs.cwru.edu/misc/AMANDA/Student_Talk_Flyer_revised.doc

another:

http://www.brushwellman.com/alloy/tech_lit/sep02.pdf

and this:

http://nepp.nasa.gov/whisker/reference/tech_papers/chudnovsky2002-paper-silver-corrosion-whiskers.pdf<

It is interesting that the NASA paper refers to silver sulfide as
non-conductive, while the first paper gives a short and tantilizing
tidbit about forcing it into conductivity.

Hope you find the links interesting!

Mike,

Thanks very much for the links. They furnished quite a bit of information about silver, its alloys, and its salts, that I didn't know. They do seem to support what I had thought about sulfide being more common than oxide, and added chloride to the list of common tarnishes. And maybe the reason for the elusiveness of information on the conductivity of silver oxide is because of the strange nonlinear effects reported in the first paper. Hopefully Jim will be able to fill us in about that, since he apparently has some information on the oxides. I'm frankly startled that any oxide can have conductivity within even a few orders of magnitude of a good pure metal, so I hope he'll post the information soon. One of the links notes that only silver alloys (particularly with copper) tend to oxidize, so in order to get a coating of silver oxide, you'd need to coat your wire not with pure silver, but with an alloy that's somewhat more resistive than copper to begin with. Does that mean, Jim, that the conductivity of the plated wire would actually improve as it oxidizes?

A paper I read some time ago showed that silver plating nearly always consists not of pure silver but of some alloy (as one of the links pointed out), and nearly all those alloys have a conductivity less than copper -- some, much less. So if you want to reap whatever benefit there might be in silver corrosion products over copper ones, you'll have to put up with lower conductivity in the uncorroded wire. Seems to me to make more sense to use enameled or insulated copper wire to begin with, but I guess some folks think the appearance of silver is worth the hassle.

The only resistivity information I have is for AgS, which is apparently a common corrosion product, and its resistivity is about 100,000 times as great as silver. This isn't necessarily bad, since both a perfect conductor and a perfect insulator provide a lossless coating. The loss incurred by conductors of intermediate quality depends on the frequency and coating thickness, so it can be hard to draw conclusions about what compound might be better than another except in a specific case.

1037. Re: Guy wire vs. guy rope

Newsgroup: rec.radio.amateur.antenna
Date: 2004-04-19 06:30:54 UTC
From: zeno <zeno@sonic.net>
Message-ID: <4083721C.AD322664@sonic.net>
Source record: 96437

Hi Richard and the group,

Excellent. I can even move the 5th mast out to add even more perimeter. The clearance at each mast will be at least 10'-15' maybe more. Your keyboard image making was appreciated.

Did I mention that the ladder-line will be perpendicular, but moving away from the loop more horizontally than as a strict vertical drop. The ladder-line will be 10-20' away from the mast at that corner and needs to span maybe 45+' to the house and then maybe another 15+' feet to the matchbox. I only mention this in case I am overlooking any precautions I may have not already considered.

It looks like the loop will have to have a bit of tension in order not to droop, especially with these dacron extensions at each mast. I was planning to have the loop wire free-flowing at each corner glass strain insulator (glass can handle the abrasion, plastic could not), except the one corner closest to the point where the ladder line-attaches in order to minimize movement at that feed point juncture.

Most of the mast materials are set to go. I still need to decide on the details of the ladder-line construction, which wire and which spacers. I will use solid copper wire because braided is too wiggly and might swarm at me. Insulated vs. bare? Bare has a certain appeal. #14 vs. #12 vs. #10 (?).
Why not #10?, it is only in the air for 45'....ok maybe that is a bit heavy, a bit overkill, maybe #12 then.... anyone ever use #10 for ladder line?

I am thinking that bare #10 (or even #12) solid copper would hold its shape especially negotiating the curve from the 4' of PVC pipe it will be tied to above the house at the edge of the roof peak, then arching down and crossing between some telephone and cable tv lines, into the the side of the house through some porcelin insulators, suspended briefly in the attic, and then down through the ceiling, again through porcelin tube insulators. In other words, after I poke the two wires through the side of the house into the attic, I will, shortly thereafter, be up in the attic continuing to attach a number of spacers to these wires (wearing a dust mask and a cob-web proof hat), until I get to that point in the ceiling where the wires will again go through the porcelin insulator tubes, then on the other side of the ceiling (in the "shack"), as the wire comes into the station, I will again be adding a few more spacers until it arrives at the matchbox, at which point, I will have a coffee break.

This way the ladder line will have no breaks from the antenna feed point to the matchbox.

hmmmmm....what if I need to add length to my ladder-line later for some reason? I will hate to cut into it!

Does 60-65' of ladder line seem like a "good" number. I will double check this meaurement tomorrow. If anything, it might be longer. Are there any particular

lengths in this type of feed system I should be avoiding? BTW, the matchbox has no 160m. Until I acquire some other balanced tuner that does, if I want to try this loop on 160m, I will have to connect it to a little balanced tuner I have here using a balun.

I have learned that a good technique for tying the ladder line to the anchor above the roof's edge is to weave some of that small dia. dacron line into each side of the ladder line and use that to pull the ladder line to the support. Anyone second this, or have another solution? Pulling on the spacers doesn't seem like a good idea.

If I have stated anything that needs advice or correction, anyone, please don't hesitate.

> > Outermost section (stub, open at inner end): 27' 5" [resonant at 40 meters?]
>
> Is this just an attempt at a trapped antenna using stubs for traps?

That's exactly what it looks like to me, Cecil. That's also how its
operation is explained in the article. Why a stub that is excited
along its length should behave as a trap is not explained, nor how the
shortened sections act as loading coils (the entire antenna is only
112' 4" long, plus connections).

Note that the antenna works as follows:

10 meters: 6'11" sections act as open circuits so that 8' sections
function as dipole.

20 meters: 13'10" sections act as open circuits so that 8' plus 6'11"
sections function as dipole.

40 meters: 27'5" sections act as open circuits so that 8' plus 6'11"
plus 13'10" sections function as dipole.

80 meters: Entire antenna functions as dipole.

15 meters: 27'5" sections act as open circuits so that 8' plus 6'11"
plus 13'10" sections function as dipole on 3/2 wavelength resonance.

> It doesn't seem to model out to be very functional.

Modeling the thing looks like a real challenge for a whole bunch of
reasons. The gaps between sections may be important, for example.

> The outermost
> stub on 40m needs to have a very high impedance, i.e. 1/4WL shorted.
> That works well to resonate the vertical on 40m, but 1/8WL on 80m
> makes the antenna resonant at 3 MHz according to EZNEC.

Lattin's results prove that it is *possible*, so your model obviously
needs work to agree with physical reality. But whether the Lattin
antenna is worth all the effort and mechanical troubles is another
story.

The antenna described is a dipole rather than a vertical, but the same principles apply.

I suspect that a key element to the antenna's operation is the use of the tubular Twin-Lead, with its 0.8 velocity factor. This stuff is probably close to being unobtanium these days. Another point is the extreme narrowness of resonance on most bands.

The W5GI antenna seems to be a variation on the Lattin theme.

For all that trouble, it seems to me that a better choice (if you want direct coax feed on the non-WARC HF bands) is the classic W3DZZ trap dipole. With only two traps and mechanically robust construction it is possible to achieve direct coax feed and low SWR on 80/40/20/15/10, and the cut-and-try is much easier.

Unfortunately, they later found out they were oppositely polarized, and the
husband had been looking up the skirt of a discone down the block.

1050. Need info on antenna issues in Minneapolis area

Newsgroup: rec.radio.amateur.antenna
Date: 2004-04-19 12:45:27 UTC
From: prjames@mindspring.com
Message-ID: <65a4e370.0404190445.2bdcaa99@posting.google.com>

Greetings all,

I am planning to move to the western suburbs of Minneapolis soon, and would like to know if there are any communities that I should specifically "look at" or "avoid" due to restrictions on ham radio antennas or other issues.

Even apart from ham radio issues, I prefer rural to urban, but commute time to the areas on the west side of downtown is an issue preventing me from being too far out. Mound is probably the western limit of what I am willing to consider.

Right now I am looking at Mound, Champlin, and Maple Grove. My realtor is generally helpful, but amateur radio is a mystery to her and I do not think she is used to getting such requests.

73,

Cathy (N5WVR)

==========

Isn't a return-loss bridge electrically exactly the same as the
common-or-garden SWR meter with the meter scale calibrated in something
different from SWR = 1 to infinity?

Same applies to reflection coefficient bridge.

I guess an Extra should be able to figure it out. I would say it would be a
lot of work to put UHF FM gear on 11 meters AM/SSB. Too much work in fact.
Now if he was going to use them on GMRS FM I would say go for it BUT it
would still be illegal as they won't be FCC type accepted. Get caught
selling these things, lose your Ham ticket.

That doesn't make any sense. UHF gear is suited to the 400-600MHz
region. 11 meters is 27MHz. You would have to completely gut the
unit and replace all of the tuned circuits.

Besides, it is very ILLEGAL to run any non type accepted gear on the
11m CB band (unless the power is in the milliwatt region.. Even in
today's relaxed enforcement environment, running funny gear on 11m can
get your ham ticket pulled.

-Chuck Harris

OBTW, you are 18 days late for an april fools joke.

Cathy: this doesn't answer your question, but might give you some food for thought. If amateur radio and antennas are very important to you then I think you are making the wrong decision about suburbs. I moved from a city into the country a few years back; not only did I not have any hassles putting up antennas but I could not believe the difference in how QUIET all the bands were. Cities are full of QRN: in fact, it is unbelievable how much QRN is generated by thousands of appliances, power lines, computers and cars. I went from a continuous S4-5 background noise level to maybe S1 on 160-20 metres. It made a HUGE difference to the pleasure of amateur radio. I was able to work stations I could not even hear in the city. It was a revelation. You could test this for yourself with a mobile HF setup if you have access to one.

These days it matters little what suburb you move into - there will always be someone who does not like tall "ugly" structures "in their neighbourhood".

Good luck with your decision.

I recently posted a question concerning mounting a glass-mount antenna on my 2000 Ford Taurus station wagon.

Some people responded saying that I should use a mag mount antenna on the trunk lid. Since I have a mag mount sitting here not doing anything, I thought I would give it a try. However, I looked all over and have been unable to find the trunk lid.

Does anyone know where it is located on a 2000 Ford Taurus station wagon?

Subject: [96966] Re: MSDOS BASIC software archive and RF Design Mag
software archive

For all those who asked about the RF design files:

Click on the "Join Now" icon in upper right corner of page and go from
there.
Involves getting MSN passport which is just e-mail address at
hotmail.com
and password of your choice.

There are nearly a hundred files so can't forward them but could any
single
file from list on that page. they are named RFDXXYY.ZIP where XXis month
and
YY is year.

I downloaded them by right clicking on each and chosing "save target
as".
Some reason it insisted on saving it as xxxx.ZIP.zip so I edited out the
..ZIP from each save as so it became xxxx.zip.

Hi Yuri

I lived in my last house for slightly over 20 years.

Although a high percentage of the welded wire fabric decomposed over that time, leaving iron in the soil, evidenced by all of my hydrangeas turning bright blue, the areas of aluminum fencing never did deteriorate.

In fact, the fencing I will be using is the same fencing that surrounded my property for those 20 years, with the lower ends buried over a foot into the ground. Not the actual fence, but a partial roll I had left over after constructing the fence. That had been in storage all this time.

If I could find a company that makes this same small weave aluminum fencing I would have them do my whole yard at my new house. But I have not found it available anywhere. Perhaps as you pointed out, it don't hold up under certain conditions.

My aunt lived in Florida for awhile, she had the same type awnings installed, by the same manufacturer even, that she had installed some 25 years earlier in St. Loo, they didn't hold up but only 4 years and were full of holes. Assumably from the salt air.

She should understand covenants. Have her look into that. Other than that, there can be township restrictions on antenna towers. Those usually don't prohibit them, but put limits on height. And you can often get allowances or exceptions.

Your requests are reasonable and to be expected. Other people make requests to find out if dogs are allowed in the neighborhood, etc, so the realtor needs to do their job. You are paying them a lot of money when you buy your house, so if they can't seem to find covenant and zoning laws, you might want to mention about finding a realtor that can.

Remember - Mr or Ms Realtor is NOT your friend.

N2EY wrote:
> The W5GI antenna seems to be a variation on the Lattin theme.

He says nobody has been able to model or explain why the
antenna works. KA8NCR over on qrz.com says it's lossy
on receive compared to a resonant dipole and about the
same as a trap dipole. I think this is the thread:

http://www.qrz.com/cgi-bin/ikonboard.cgi?s=4083e6f2738bffff;act=ST;f=5;t=60158;st=10

Looking at the W5GI antenna, it would seem that reflections
from the ends of the antenna would flow towards the feedpoint
on the coax braid due to skin effect and encounter an open
circuit. If one sent a TDR pulse toward the end of the antenna
from the feedpoint, what do you suppose one would see coming
back?

The city of Plymouth should be on your list of candidates. We have a very ham-friendly antenna ordinance which I wrote. You can put up a 70-foot antenna support structure without any variance needed.

Regardless of which city you select, be aware that a particular developer or homeowners association may have restrictive covenants in the property deed. Your realtor should be able to uncover those on properties which interest you.

73, and welcome to Minnesota,

There used to be something called Class A citizens band, which was AM modulation... I think on 460 MHz. There were a bunch of tube transmitters built for that band, most notably the Vocaline, and some of those can be sort of tweaked to kind of run on 440 MHz if you don't really care much about stability. A lot of them used bend-until-it-works capacitor and inductor technology.

I do not think this is a currently usable band. Although if it WERE currently usable, Fair Radio has a bunch of UHF AM aircraft transceivers for the military air band, which they are practically giving away right now. Not type-accepted of course...

>IF NOT, WOW..... that is a task and a half. As others have stated,
>legality will be out the window. Lou

The 11M crowd has never been one for worrying about legality. Which is kind of a shame since there's clearly a need being met there.

You might start by getting the ARRL book, "Antenna Zoning for the
Radio Amateur." And then hire a Minneapolis attorney who specializes
in real estate issues.

I don't know anything about Minneapolis in particular (except for MSP, with which I am too well acquainted), but I recommend that you *insist* on getting information about any CC&Rs and/or Home Owners' Associations that pertain to the particular subdivision or lot in which you are interested.

We bought a house in W. Michigan last year in a 30-yr old subdivision with minimal CC&Rs (with no mention of antennas or transmitters), no HOA, and underground utilities. Although most municipalities around here exempt amateur radio towers/antennas up to 70ft from any zoning ordinances (and the township in which we bought does not even require a building permit for a tower to ensure that it is safe), all the newer properties we looked at had draconian CC&Rs specifically outlawing anything more than a small satellite dish mounted no more than a few feet above the roof. You *must* check out the CC&Rs before signing anything, as they typically "run with the land," are recorded at the local "Registry of Deeds" (or whatever), and are enforceable even if you have never seen them -- the CC&Rs for the property we bought were not even made available at the closing (and even if they had been, that would have been a little late to back out of the deal).

I have built a few of these and they do work. As always, smaller means some compromise. I have a 17M, 40M CW, and a 40M Phone Microvert in my attic. They are pretty easy to build (if you know a little math) and not all that hard to tune. I would recomend playing with one. My 40M antennas are about 3 feet tall and I have no real problem working most stations I hear. I usually run PSK at 20-30 Watts and have worked some DX and lots of stateside. It won't beat a 30 ft vertical in the yard but it does work.

Some pictures of my first attempt can be found here:

Helical Beam is great at 400 MHz, could be too big for 137. Nasa, mil have them. About 1 wavelength in circumference, 2.5 foot diameter, 5-6 turns, circular polarization, and can be pointed at satellite. Circular pol needed usually as most satellites tumble.

other signals out there at:

Hi Jim,

Simply because the so-called explanations are more wish than reality.
I've not slackened my study of this design. I've done thirty or forty
measurements that have interest in their own right, but show the
"theory" is sheer fantasy. These notions of tuned stubs as traps are
so far off the mark in practice that no one notices they don't make
sense electrically either.

>
>Modeling the thing looks like a real challenge for a whole bunch of

These apologies ring false. The issue of gaps is desperate and the
selection of tubular has no basis in special characteristics. All
such considerations MUST yield to simple scaling. For instance, if
you need 0.8 and have 0.9, there is no magic formula beyond
proportions necessary to achieve "what should be."

The difficulty lies in the supposed explanations.

>The W5GI antenna seems to be a variation on the Lattin theme.

And it is even more gauche. It approaches antenna design as an allied
art of Palmistry.

Hi OM,

Yes it would. It is against the law to sell Transmitters that are not
type-accepted for the band they are intended.

On the other hand, the Amateur radio service is the ONLY exception to
the rule. We CAN design, build, and operate non type-accepted gear.

On the third hand, the 11 Meter band is not Amateur radio service.
Even tho' we can work there, we must abide by all rules and
regulations for that service (all restrictions apply in spite of our
"privileges").

Considering the GP that is normally used with this antenna for elevated mounting it should work quite well with what you have. I would probably want to mount it in the center of the roof and run 4 wires from the antenna to the corners of the roof bonding the wire to each metal panel it crosses. One problem with doing this is that bad connections with adjacent panels could cause noise on recption and intermitent changes in tunning during transmit. Just be aware of what you may have to do to fix some strange intermittent problems.

Quite right. Converting existing equipment to 11-meter use would
probably require individual certification of every unique piece or
type. Sure sounds expensive.

Issue 2: external power amplifiers are not allowed in the 11-meter
band... conversion of higher-powered UHF amps would not be legal.

Issue 3: equipment originally designed for UHF operation (1 meter and
shorter wavelengths) seems to me to be a less-than-wonderful choice
for conversion to 11-meter operation.

Issue 4: there's plenty of cheap 11-meter gear already on the market
(both legal-type-certificated, and outside-the-pale). Doesn't seem
like there'd be much of a [legal] market for converted UHF gear.

All in all, this idea sounds like a great way to lose lots of money,
and risk big fines and the loss of an amateur-radio license. As folks
may have noted, the FCC has recently raised their level of enforcement
against companies and individuals who have been playing loose-and-easy
with the rules about 11-meter operation and equipment sales.

Hi Bob,

I did pick up a 500' roll of #12 insulated from the Home Depot here (current price here is about $32), but it seems like this braided copper will require too many spacers to keep it straight. I am thinking about returning it for some solid copper #12. I think the solid will hold shape better as a ladder-line with a minimum of spacers. Also I see no reason not to go with bare wire instead of insulated.

Can anyone run down the pros and cons of bare vs. insulated for ladder-line. I understand there is ever so slightly less loss with bare wire.

Bill

The Armenian judges gave this a 9.8 on the Olympic Troll-O-Meter, but they were over-ruled by the umpires in instant replay, who award it a 1.4.

The Armenian judges lodged a formal protest!

It was sufficiently trollish, of course, but way too obvious. It was poorly written, poorly executed, and was so incredibly lame as to lack the true drawing power of a really masterful troll.

Maybe as high as a 1.6 for the intense stupidity of the premise, but a 9.8? Never!

The Armenian judges tear their hair out, throw their balalaikas down in dismay, and perform the traditional Armenian Dismay Chant!

They demand a recount!

Hi There,
I wonder if there is a better way to feed my 1/2 size G5RV......

At the moment I am using it portable with the apex at 30 feet and the ends sloping down to 3 feet above ground .....the DX location is around 250 mtrs ASL.

It is fed by 300ohm ladder connected to 20 feet of 50 ohm coax.

is this the best way to feed it I have heard that just using ladder line is better/more eficient...

I would be gratefull for any plans or suggestions on how to feed this or plans of other more efficient/easy set ups for portable "WIRE" antenna set ups as I like to make my own antennas ....

I would like to over come the qrp operating by hight and antenna eficiency...

Thxs for any suggestions......

I recently lengthened my 44-ft dipole to 51 feet, so it is a 1/2-size
"g5rv". I feed it with 42 feet of 450-ohm line, because that is what
it takes to get to my window. To transition to my tuner, I have a coax
choke balun at the window. With the tuner, I can work all bands from
40 thru 10, except for 15 meters, where the swr is a little high.

Whether this is better or worse than what you have, I couldn't say,
but it does work.

I suspect your antenna would work fine, fed entirely with 300-ohm
line.

I agree that any intermittent contacts in the roof metal CAN make noise.
Even if the wire is routed as suggested. Receive is covered above... During
transmit there are two effects to watch for.

Any noise caused by bad connections in the wind WILL *modulate*
your transmitter with the same noise. Most likely, this won't cause a
problem for you except to other radios close by. However, the frequency
range can be extensive. On Apollo communication ships the HF transmitters
caused interference to the on-board *radars* because of the junk caused by
the deck railing chain links. Whatever the noise spectrum looks like, this
can cause an AM on your signal with the same shape sidebands. Because your
transmitter is right there and part of the antenna current is flowing in the
roof, the effect can be rather strong. On sideband I think this could sound
like splatter. Bottom line, I think is increased possibility of TVI or BCI
for the nearest neighbors.

The other is increased ability to make Intermodulation (IM). This
should only be a problem if you have two transmitters operating. This is
the sum / difference and 2A-B type of IM caused by partly rectifying

junctions in the corroded metal.

I'm just learning so here's what I know. A RLB is a directional coupler with directivity, isolation and a bridge. Return loss is the reciprocal of the reflection coefficient. A basic RLB has 3 ports, source or input, output or DUT, and coupled or reflected. Connect a piece of coax to the DUT port, a sig gen to source and a meter to reflected. A shorted or unterminated coax will reflect 100% less round trip line loss so the meter will read launch signal less 2 time line loss. If the coax is properly terminated the meter can read anywhere from 30 to 60 dB down, depending on how well terminated in relation to the coax impedance. If you use a tracking generator for the source and a spectrum analyzer on reflected for the meter you can sweep a filter, antenna or whatever you're interested in. Retrun loss is the fraction of power that isn't absorbed by the load. See QST April 1959 pp 24-28 for Warren Bruene's article, "An Inside Picture of Directional Wattmeters."
A retrun loss 1 dB is a VSWR of 17.4, 6db RL is VSWR of 3, 10 dB RL is VSWR of1.93, while a RL of 30 dB is a VSWR of 1.06 and this can be done at low power which is quite difficult with SWR bridges.
Two hams have told me that they've made RLBs that achieved 60 dB. That's my project if I can get the article.

Cathy,

From experience, I would advise you not to depend on realtors, or anyone else who has an interest in the sale, to inform you concerning restrictive covenants. It's really not in their interest. The best thing to do when you find a property in which you are interested is to go to the courthouse and look up the information yourself.

73,

Am I mis-understanding or mis-interpreting something, or
doesn't 11-meter stuff have to be "type accepted"?

I can't imagine homebrew conversions being "type acceptable"!

No, the experimental service is also available for people who want to
run non-type-accepted equipment.

I _think_ there might still be a provision under Part 73 to allow broadcast
stations to operate non-type accepted transmitters under certain circumstances
if they can provide measurements that the equipment meets the standards of
the type requirement, and they affix a label to the equipment. I seem to
recall that it only applies to equipment built by the station itself. This
may have been removed from the rule book since I took my First Phone test.

>On the third hand, the 11 Meter band is not Amateur radio service.

I have lived in the countryside (1 acre lot, well, septic system, yagi
on roof for TV reception) for years and loved it, but I fear that the
commute time in the Twin Cities will be significantly longer per mile,
and I am not willing to buy into 1 hour+ commutes each way. What
good does it do to get quieter living space (both radio and sound)
if all my free time gets taken up by the commute?

> These days it matters little what suburb you move into - there will
> always be someone who does not like tall "ugly" structures "in their
> neighbourhood".

Well, I wasn't planning to put towers up. But I am hearing horror
stories of people who have been hassled just for stringing a few wires
around their yards. I also have personal memories of causing QRN
to the neighbors back when I lived in an apartment, and that experience
was negative enough to push me out of the HF spectrum for a few years.
I am just now getting back in. (Those consumer lamps that are switched
on and off by touching them think that a passing wave on 15 meters
is a hand touching them and telling them to turn on...makes CW very
interesting to the lamp owner. I fixed that problem by putting chokes
on the neighbor's lamp cords, but I'd hate to do that for every neighbor,
and the problem still existed on 40 meters.)

Getting back to Minneapolis: I would appreciate it if someone
living in the area could give me some very specific guidance on
issues such as "how far west do I have to go to escape the worst QRN",
"how far do I have to go before the area feels rural," and "can I
get a rural feel with a commute to downtown of less than 1 hour
each way". I am in a position where I will probably end up buying a
home without living in the Minneapolis first (coming in from out of
state), and I do not want to make a mistake.

Cathy:

First off, you need the services of a good *real estate* attorney. Not just any lawyer will do; you need someone who does RE as a specialty and who deals with CC&Rs (codes, covenants and restrictions) on a daily basis. Make sure the attorney understands that his/her job is to dig up any and all restrictions on any property you might be interested in *before* you sign anything.

Second, require that you and your attorney be provided with a complete and up-to-date set of the deed, title and all covenants and deed restrictions *before* you make an offer, and read them thoroughly. Sometimes they are part of the deed/title itself but often they are not. States differ widely and you may need to be a bit insistent on what you want to see. Almost all properties built in the past 40-50 years have some sort of restrictions, and those built in the last 30 years often have lots and lots of restrictions of various types. Note that most restrictions are intentionally designed to be *impossible* to change, and that by signing on the dotted line you agree to abide by *all* of them.

Third, try to educate the realtor. Show her some typical amateur antenna installations so she has a better idea of what it is you want to put up. Terms like "antenna tower" mean different things to different people.

Fourth, realize that most but not all of the people involved in a real estate transaction only get paid if you actually buy a house. No sale = no comission/fees/taxes.

In my case the realtor and attorney were able to get me a complete copy of the restrictions fairly easily. They were *not* part of the deed/title documents - instead, those documents referred to the restrictions, which had to be retrieved from the county courthouse records. I had to ask specifically to see them early on in the transaction - if I hadn't insisted, I would never have seen them at all. Until somebody complained.

Even though my house is over 50 years old and there has never been any sort of home owner's association, there were a page and a half of restrictions. Most of them seem a bit comical today (no raising livestock on a property that is 60 x 120 feet) or have been superseded by more-restrictive township ordinances (setbacks, advertising signage, noise). No mention of antennas but I can't have a freestanding tower (or a shed) with a concrete base because that would constitute a "structure" and only the house and garage structures are permitted.
Doesn't matter to me because there's no room for a tower anyway but that's the sort of thing to look for.

Good luck!

73 de Jim, N2EY

You'll also find information about return loss bridges and how to construct and use them in Hayward, Campbell, and Larkin's _Experimental Methods in RF Design_ (ARRL) and its now out-of-print predecessor _Solid State Design for the Radio Amateur_ by Hayward and DeMaw (ARRL).

I think the rules say "no more than 5 (or is it 10) copies of the same
design per year.
Manufacturers who want to make more than that *do* have to get
certificated. That's
what the FCC calls "type acceptance" nowadays.....

Well, there are several different allocations there. There's the
infamous CB band, and various
forest ranger, mil and other such where the "freebanders" operate
illegally.

Sad to say, the legitimate users of those latter bands are being driven
out by the FCC's refusal to do anything about the freebanders. God knows
that the auxiliary broadcast channels at 26 MHz are constantly being trashed.
I've had to move some government comms to 33 MHz where things are a bit
quieter.

Just as an aside, it might be worthwhile to drive around a prospective purchase area and just look for antennas. A couple of polite questions might tell you a lot about what is possible.

It might also be worthwhile to Google for amateur radio clubs in the area to see if they have a feel for local conditions. While neither of these will necessarily be binding on your particular property, they might give you a general clue to the area.

For what it's worth, I live in Daly City, a suburb of San Francisco. This area was built across the 60s. I'm not aware of any local restrictions, but I have two ham friends within a few blocks, one of whom has a few slopers and verticals on his roof and the other of which has about a 60 foot crank-up tower in his back yard with a yagi that barely fits within his own property lines (maybe a 25' x 150' lot).

Westlake, an area closer to San Francisco, maybe even part of Daly City for all I know, has extensive CC&Rs, including requirements to keep your house painted in an acceptable color and to keep a living palm tree on your living green (grass only) lawn (even those whose houses are sliding into the Pacific Ocean, aided by pumping all that water into the ground. Some of the earlier restrictions, like those restricting sales to certain ethnic groups have been overturned by courts and some sections of that subdivision are now easing or abandoning some of the restrictions as the opportunity for the residents to re-vote on them comes up.

All of which is to say that conditions may vary greatly within short distances, whether in urban or rural areas. So I have to agree with the earlier posts which note that the Realtor (tm) -- yes it is a restricted term than just anyone may not use -- is working for the seller and that involving a knowledgeabla local real estate attorney is your only guarantee.

Dear Ms. Cathy:
I ran a township zoning board for 18 years. My experience is that real estate agents (by whatever name) will tell a buyer anything! to make a sale. Most of the serious problems dealt with by the board came from buyers believing "their" agents. The agent is not your friend.
[The only honest agents that I encountered were involved with million dollar sales with several lawyers (on each side) keeping them honest, and one other agent who became so appalled at the lack of ethics that she quit.]
A lawyer with experience in real estate is your best defense. Even so, check and double check. You have been provided with some good advice.
Consider the long term benefits of a slightly longer commute time.
In Michigan, 10+ A. is a farm and is treated better than a lot. Raising antennas is best done on a farm.
Good luck. Remember that the agent, as friendly as she or he may seem, is not working in your interest. Verify.

I don't know about hiring an attorney first off, Jim. Over the course
of buying a hous, I looked at maybe 30 or more. Sorry, I just don't have
the money to pay an attorney to investigate every house I looked at.

When the field got really, really narrow, then perhaps

> Second, require that you and your attorney be provided with a complete

Maybe for a little kickback? Seriously, that is the job they are
supposed to do, and considering th eamount of commission they get, they
are supposed to find out things you need to know.

Mind you, I don't think very highly of most of them. I could tell you
about the time that we took a tour of a house that was already sold. Or
the time we put a down payment on a house that the agent "neglected" to
tell us was in a flood plain until the day after the check was cashed. I
told him he had exactly 30 minutes to repay us the money. Took 15.

> Fourth, realize that most but not all of the people involved in a real

Part of their job, like asking to see only green houses. Or not green
houses.

I got lucky when I bought my house. I could put up a 40 foot tower
without a problem, and no restrictions on wire antennas. I say lucky,
because I didn't become interested in the ARS until after we were in the
place for 5 years or so.

Not entirely accurate... at least, not yet.

They have proposed rescinding the Part 97 rule which places a whole bunch of restrictions on the manufacture and sale of amplifiers which can be used between 24 MHz and 35 MHz (the 10- and 12-meter amateur bands, and the 11-meter CB band). This change has not actually been enacted - they're inviting comments on whether it's a Good Idea or a Bad Idea.

They have _not_ proposed making any change to the Part 95 rules, which currently make it illegal to actually _use_ any such amplifier with an 11-meter (CB) transmitter.

So - if their proposed rule change is adopted, it'll be easier for amateurs to buy amps that can be used on 10 and 12 meters. General-purpose HF-band amplifier designs will probably be revised, to "open them up" to the higher frequencies.

It will still remain illegal to use any such amplifier on the 11-meter CB band.

Whether this illegality will stop anyone... well, that's another question entirely!

Good evening, Gentlemen.

A thought experiment:

Start with a regular 1/4-wave monopole ground plane. The literature says it looks like half the value of a dipole, about 35 Ohms, when resonant. It would be nice to have the resistance at the terminals be a bit higher, and I very much value a grounded element anyway, so let's let it evolve into a folded monopole. The literature says it should now have about 4 times the terminal resistance of the original 1/4-wave we started with (about 140 Ohms). Huh. Now it's a bit high.

They tell me that shortening the antenna below resonance will lower the resistance and introduce capacitance. But I think I have also seen in the literature that the antenna can be viewed as a transmission line. A shorted portion of parallel conductor transmission line (the folded monopole) less than 1/4-wave long looks inductive. But wait! Which will win? Will the shortness of the antenna look capacitive or will the transmission line dominate and the antenna will look inductive?

Even better, is there some choice of the folded section wire diameters and spacing that will give an inductance that will exactly offset the capacitance due to shortness? So, then, is there a folded monopole of such dimensions that the resistance is 50 Ohms (due to being shorter than 1/4 wave) with no terminal reactance (due to the inductive design of the "transmission line" cancelled by the shortness of the antenna's capacitance)?

Brain hurts.

John, KD5YI

The literature says it should now have about 4 times the terminal resistance of the original 1/4-wave we started with (about 140 Ohms). Huh. Now it's a bit high.

They tell me that shortening the antenna below resonance will lower the resistance and introduce capacitance. But I think I have also seen in the literature that the antenna can be viewed as a transmission line. A shorted portion of parallel conductor transmission line (the folded monopole) less than 1/4-wave long looks inductive. But wait! Which will win? Will the shortness of the antenna look capacitive or will the transmission line dominate and the antenna will look inductive?

Even better, is there some choice of the folded section wire diameters and spacing that will give an inductance that will exactly offset the capacitance due to shortness? So, then, is there a folded monopole of such dimensions that the resistance is 50 Ohms (due to being shorter than 1/4 wave) with no terminal reactance (due to the inductive design of the "transmission line" cancelled by the shortness of the antenna's capacitance)?

Brain hurts.

As does the G5RV Application Note from Antennas West.

Unfortunately, a folded monopole goes the opposite direction to a
monopole, impedance-wise.

Message-ID: <10892fqqfas8p01@corp.supernews.com>
Source record: 96277

The short answer to your question is no, with practical impedances. It turns out you'd need a very low impedance transmission line (on the order of a few ohms, if I recall correctly) to track very well.

The easiest way to analyze a folded dipole is as two separate circuits, common-mode (or "antenna") and differential-mode (or "transmission line"). Superposition applies, so the two can be analyzed separately.

First consider the "antenna". Its contribution to the feedpoint impedance is the same as a conventional monopole made from the two wires in parallel, but multiplied by 4 due to the transforming action of the "folding" process. (Other ratios are possible -- 4 is what you get if the conductors are the same diameter.) This "antenna" does all the radiating.

In parallel with the "antenna" at the feedpoint is the "transmission line". This is the short-circuited transmission line made from the two conductors, with transmission line velocity factor taken into account. The "transmission line" part does no radiating.

Now, if you shorten the antenna, two things will happen. The reactance of the "antenna" will become more negative, and its resistance will drop some. This will show up at the feedpoint just like it would for an unfolded monopole, but multiplied by 4. But you're also shortening the transmission line, whose impedance also appears at the feedpoint, in parallel with the transformed "antenna's". Assuming negligible loss in the feedline, this will cause a change only in parallel reactance at the feedpoint. Because of the relatively high impedance of the transmission line, and the relative sharpness of the impedance change of the "antenna" compared to the transmission line, there's very little compensation in the case of most practical antennas. Remember that the two impedances are in parallel, not series, so the high Z contribution of the transmission line has little overall effect. As I recall from doing an analysis some time ago, you get more broadening compared to a conventional monopole from having a fatter equivalent "antenna" conductor than you do from the transmission line stub.

The reactance of the "antenna" can be a bit tricky to calculate accurately, but a number of modern programs (such as the free EZNEC demo) do a good job of it. The transmission line part of the effect is easy, either with a scientific calculator or one of the transmission line programs which are readily available. So overall, it's not difficult to find the actual impedances you'll see in practice.

John:

Andrew Corp. made a good living back in the dark ages (40s-60s)
manufacturing and selling 50 ohm folded monopoles. I can go measure the
element diameters on mine if you are interested. If I can recall where it
is stored. It uses a small inductance at the feed point for matching.

I lived in Daly City (St, Francis Heights area) from 1977 to 1985
and there were no restrictions on the 1960-era house and lot.

>Westlake, an area closer to San Francisco, maybe even part of
>Daly City for all I know,

Yes, the Westlake District is an integral part of Daly City that was
the first tract development by Henry Doelger post WW-II (in fact
when one says "Daly City" one thinks of Westlake first).

>has extensive CC&Rs, including requirements
>to keep your house painted in an acceptable color and to keep a living
>palm tree on your living green (grass only) lawn

That requirement was overturned as unreasonable by a court case in
the early 1970s.

My kids, OTOH, live in one of the condos up near the water tanks in
the foothills of San Bruno Mountain (still in Daly City) and there
are CC&Rs up the wazoo. For obvious reasons they did not seek my
legal advice or assistance before they bought the (obscenely-priced)
property - no big deal, neither of them are hams.

> All of which is to say that conditions may vary greatly within

>seller and that involving a knowledgeabla local real estate attorney
>is your only guarantee.

Now for Cathy -

Make your receiving, examination, and acceptance of all the
restrictions (CC&Rs and any Homeowners' Association Regulations)
a contingency of any offer, and get some advice from a local
ARRL Volunteer Counsel who can give you local information of the

sort that Hans gave you about Plymouth. VCs are listed on the ARRL web site - you should touch base with one first.

Also it would not be a bad idea to touch base with Jay Bellows, K0QB, the ARRL Dakota Division Director who lives in St. Paul. Jay is one of a handful of us attorneys who deal in zoning, permit, and legal issues involving amateur stations on a regular basis, and was the attorney who was successful in getting the key U S Court of Appeals ruling in _Pentel v Mendota Heights_ upholding the FCC's requirement that a municipality must give "reasonable accomodation" to amateur antenna structure applicants.

I can only wish you good fortune in finding a place that suits your needs.

You will save yourself a lot of grief by visiting the city or county
planning and zoning (P&Z) office, and or maybe the codes enforcement
office if there is one. Ask them what restrictions are in the
ordinances. Keep in mind that if the neighborhood you are in has
protective covenants, those may be a matter of law (ie the developer
submitted them to the city/county and when his development was
approved, the covenants became part of the zoning or plat). Even if
the covenants are not part of the city/county zoning/code, by signing
the did you may be signing compliance with any restrictions/covenants.
These could amount to a legal contract, and herein is where only an
attorney can tell you how hooked you are and/or what your options are.
Good luck!

Thanks, George, but the inductor at the feed point is disqualified. The idea was to learn if everything could be done by just clever design. It appears not.

But, thanks for your offer.

John

Tony,
What you heard about feeding a 'G5RV' more efficiently with
some type of 'ladder' line is correct. 'More efficient' is
relative though.
Just for 'grins', the 'ASL' height is sort of meaningless for
DX or local, makes little difference, in general. 'AGL' does
make a difference, since it is one of the factors which will
shape radiation pattern, impedance, etc. (If it's a choice
between a (+) ASL and a (-) ASL, I think I'd take the (+) one.)
'Doc

They could be had in stainless steel and they were tough. Like Andrew cables and connectors, it was wrong to use anyything else.

I can attest, having used countless numbers of the above, that Andrew`s folded monopole when ordered for the precise frequency and mounted atop your tower gave a full forward power indication on your wattmeter with nearly zero indicated reflected power which meant a good 50-ohm match. All you had to do was install the antenna right and it would give optimum performance for many years. Your signal reached as far as the eye could see and then some. Your radio heard signals acutely.

Well grounded to the tower at the top and with proper grounding of the tower and transmission line at tower top and bottom, lightning is routed to ground and not to the inside of the attached radio. The antenna just shook off the lightning strikes with small pits as calling cards. No harm done.

Best regards, Richard Harrison, KB5WZI

Source record: 96287

I tried practicing making some diy ladder line with a couple of spacers and a variety of wire: stranded #12, and solid #12, and then solid #14 (all insulated).

I think I am going to pass on this process. The only way I can see this homebrew ladder line holding its shape (spacing configuration) is to keep it under quite a bit of tension, a situation which may not actually be appropriate to my specific installation parameters here.

I am now thinking: how bad could those commercially manufactured window lines be?

Any recommendations on a specific type of commercially made window (ladder) line? I see that it comes in a variety of configurations and slight differences in Z.

This feed line will be for a full wave 160m loop.

I am not all that convinced that the effects of weather on this commercially available balanced line would be that much more negative than what it would be with any homebrew line I could construct.

I am under the impression that homebrewed ladder line should strive to have as few spacers as possible, eg. 3' for straight runs, 1-2' for curves. Using these guidelines it seems like what I would come up with would not maintain a precise spacing and the temptation would be to use a spacer at every foot. Wouldn't it be undesireable to use so many spacers?

Somebody out there must like commercial window ladder line?

Bill

Why not try a double layered loop? Feed with a 4:1 balun about 1/4 of the way from the corner on the 40 ft side, make a spiral, and send the other side back to the balun. Separate the two layers by about 10 feet, get it at least 15 feet off the ground at the bottom, and it should work.

In that small of a garden, you're going to have to compromise.. might as well get as much wire in the air as you can.

Hi Bill,

You repeatedly characterize this as 160M and given the size and height - Why do you think you need ladder line when it will in all probability fit quite nicely into a coax?

In free space, it may show as much as 140 Ohms R; however, within the cold embrace of earth only 50 feet away, you will barely muster 35 Ohms at resonance.

When transmitting what effect does moisture and/or precipitation have on various kinds of antennas, also what is the effect of rain on say uninsulated ladder line.

What is the general effect of moisture on antennas and feed lines as power is increased?

Bill

1142. Re: RF Design 90s RLB article ?

I have built a design out the ARRL handbook using a toroid transformer, and SM 100 ohm resistors in parallel to make up the 50 ohm sections. I could get 40 dB return loss to about 50 MHz, when matching a 50 ohm load. This gives an idea of the accuracy of your bridge, ie the higher the return loss in this situation, the better the bridge, assuming an accurate 50 ohm load. I used a spectrum analyser as the detector and the venerable HP8640B for the source.
You can even measure small inductances (I got reasonable accuracy to about 100nH) using a series RLC combination on the end of a length of coax as the unknown load. (ie do it remotely!) R=50, C=is known, L is unknown
At some frequency there is a max return loss. At this freq XL=XC and X(LC)~0, assuming perfect components. Thus the load is 50 ohms. You can work out L knowing C

That also answers most of Reg's question about the difference between an RLB and an SWR bridge.

As Reg has often pointed out, the so-called "SWR bridge" is actually a reflection coefficient meter and it generally includes its own RF voltmeter.

An RLB generally doesn't, but has an RF output port for the reflected signal. That port is intended to be connected to a sensitive external RF power detector - such as Richard's spectrum analyser - which can accurately measure reflected signals down to -40dB... or even lower if you consider such readings meaningful.

Another difference from the normal SWR bridge is that an RLB is always a true bridge, with separate 'unknown' and 'reference' ports.

Normally your standard Zo load lives on the reference port, but if you remove it, you can then use the RLB to compare *any* two impedances that are intended to be the same (for example the two halves of a stacked yagi array). You can see how alike the two impedances are, without actually having to measure the value of either one... a very handy feature.

Copper radials could be better.

Ed Laport who worked with Brown, Lewis, and Epstein at RCA wrote on page 121 of "Radio Antenna Engineering":

"The radial disposition of wires in a buried or surface ground system is dictated by the natural paths for returning ground currents. Meshes opf crossed wires which were once widely used, should not be used with vertical radiators because the return paths are not direct and eddy-current losses in the closed loop circuits of the mesh can be appreciable."

There may actually be a market for converted UHF gear for CB. The key here
is CB, NOT 11 METERS. Some countries in Europe have FM CB. I don't know what
the frequencies are, but quite likely VHF or UHF.

Other than that, for anybody still reading this thread - ever hear of a non
amateur UHF SSB radio?

In general, this thread is in the same line as converting old black/white TVs to color.

>Bad Idea.

I'm feeling it's a good idea. It's a good idea first of all because it
will now make it legal to sell a lot of those military surplus wideband
DC-to-daylight amplifier systems.

And it's a good idea secondly, because the CB crowd already has bootleg
linears and there is already a substantial underground selling the things.
If it's legal, maybe at least more of those guys will be using clean
linear amps that aren't bandsplatter machines. If the FCC can't stop
the sale, they can at least try to reduce the sale of the worst amps out
there.

Mike & Cathy,

Sorry if I wasn't clear about the attorney's role. My point was that
the thing to do is to line up a good RE attorney right away, with the
understanding that when you are seriously considering a particular
house you'll have the attorney research it.

In my local RE market, things move so fast that you need to have all
your people ready to go beforehand. MN may be different, though.

In a perfect world, yes. But fewer than 1 in 100 Americans is a ham,
and many hams are in the same family, so the chances are good that a
given RE agent will have little or no experience with antenna
restriction covenants and such.

I used 300 ohm TV twin lead for years. Why the concern about 600 ohms? It really doesn't matter unless you have a 600 Ohm feedpoint. The losses are still very low regardless of conditions, and as for dirty or rain, I had some up from 1983 to 1996 -- and never noticed any changes. When I took the antenna down the twinlead was as good as new and I used it for other things.

I disagree! In the QST article, Lattin describes an 80/40 dipole using
his method. It has wires dangling from the stub junctions to get 40
meter resonance.
>
> The difficulty lies in the supposed explanations.
>
Agreed. They are oversimplified at best and just plain wrong at worst.
However, I take it as a given that W4JRW got the results he claimed
from the antennas he built.

The fact that people report so much trouble duplicating and modeling
the W4JRW antennas indicates to me that there is more to it than meets

the eye - and maybe more than met W4JRW's eye, as well.

Most important to me is that the antenna offers no real advantages over, say, a conventional trap dipole. Yet it offers many disadvantages, such as mechanical frailty and difficulty of duplication.

> >The W5GI antenna seems to be a variation on the Lattin theme.

HAW!

And again - what advantages does it have over, say, a W3DZZ trap dipole?

Here's the 600 ohm concern. A dipole's feedpoint is likely to vary from
about 60 ohms min to about 6000 ohms max. With 300 ohm line, the SWR varies
from 5:1 to 20:1. With 600 ohm line, the SWR is relatively constant
at 10:1, i.e. 600 ohm line gives more consistent SWRs over the entire
HF range than does 300 ohm line - just my two cents.

How short?

There's nothing magic about a trap dipole of any flavor, be it W3DZZ
or W9INN or whatever. At their very best they're *almost as good* as a
plain vanilla half-wave coax-fed dipole. Their main advantages are:

- they can be made mechanically rugged

- they can be directly fed with coax and yield reasonable SWR

- they can be built and adjusted with relatively simple tools and
materials

> Now I just have to learn how
> to make traps. Any recommended resources for this sort of thing?
>
W4RNL's site, of course. Some time back I did posts describing
coaxial-cable traps which you can google up.

The main trouble with trap construction is the materials. Ideally we
would use fixed vacuum capacitors and big Miniductor-like coils of
heavy wire or tubing. In practice we often settle for something
less...

1) Conventional LC traps - These are usually made from transmitting
capacitors like the 850 series and Miniductor coils. An alternative to
the Miniductor is to wind heavy wire on a piece of PVC pipe, which can
also serve as an insulator. Main problems with this construction is

getting theparts and weatherproofing.

2) Coaxial-cable traps - These are made from a piece of coax (RG-58 is probably best) wound on a piece of PVC. Articles by N4UU (QST December 1984, IIRC) and W8NX describe various flavors of coaxial-cable traps, as do the posts I made here some years back. The main problem with this method is that the results are highly variable, depending on the coax used. Depending on the loss of the outer coax jacket, one builder may have much more loss in a trap than another. Adjusting these traps isn't easy. Their main advantages are ruggedness and
low cost.

3) Bifilar or "twintraps" - These are similar to coax-cable traps, but are made by bifilar-winding a pair of wires and connecting the ends series-aiding. The internal distributed capacitance makes the C and gthe coil is the L. If wire with low loss insulation is used, these should be better than coax-cable traps.

Note that not all trap dipoles are "W3DZZ" trap dipoles. That designation belongs to a specific design, which works as follows:

Each dipole half consists of an outer section (about 22 feet), a parallel LC trap resonant on 40 meters, and an inner section (about 33 feet) which is also resonant on 40 meters. Direct coax feed or 1:1 balun.

The "trick" is in the LC ratio of the traps.

On 80 meters, the traps are below resonance, and act as loading coils so that the ~110 foot long antenna is resonant on 80

On 40 meters, the traps resonate and are essentially open circuits. Thus the middle 66 feet operates as a 40 meter dipole.

On 20 meters, the traps are above resonance and act as capacitors so that the entire antenna is 3/2 wave resonant.

On 15 meters, the traps are above resonance and act as capacitors so that the entire antenna is 5/2 wave resonant.

On 10 meters, the traps are above resonance and act as capacitors so that the entire antenna is 7/2 wave resonant.

The problem is that there are 5 resonance points to hit but only 3 variables to play with (inner section length, outer section length, LC ratio of trap). So in real life the antenna can only be truly optimized on 3 bands unless you are very very lucky, or use methods such as extra "dangle wires" to establish resonance on certain bands, as is sometimes recommended for getting a 40 meter dipole to work on 15.

If I had my druthers, I'd just use a plain dipole fed with ladder line (the real stuff, not "Twin Lead with holes" and a true balanced tuner. But mechanical considerations at my present QTH make coax feed a must,

so I make do with a homebrew trapper.

I'm sure it could vary to freq being used, but overall, very little.
Rain will not have much effect on ladder line, unless there is a way
for water to bridge the gap between wires. You will see increased loss
with twin leads, but very little with ladder line that has mostly air
between the wires.
>
> What is the general effect of moisture on antennas and feed
> lines as power is increased?

Well, again could vary, but overall not a whole lot in general. With
my coax fed dipoles, it doesn't matter if it's raining or not up to
1500w. There is no difference in performance. I could see water maybe
having more of an effect on say real high freq antennas. UHF, etc..
HF, there is little difference unless you have a problem caused by
water. IE: waterlogged coax, twin lead that is wet, etc. MK

I don't think double layering will have much change, except for where
it's resonant. It should still act pretty much the same as a single
turn loop of that size.
Myself, I think he would be best off going with a very high
performance short vertical. A loop is gonna be a skywarmer, and a
lukewarm one at best. I would layer the garden with almost solid
metal, preferably copper wires, or whatever, and run the best,
tallest, lowest loss vertical he could get away with. I'd top load it
if at all possible. That will greatly improve the current
distribution.
With a good vertical, he would at least have a chance of having a
decent signal.
For long haul, nothing else he could install would touch it. I like
the inv L idea, but I assume he can't do that for some reason.
>
> M3 wrote:
> > Hi,

> > Any designs for a small antenna to work on 160M? My garden is approx 40ft x
> > 17ft.

If you line that garden with a lot of radials under the ground, you
could have acceptable losses for what you have to work with. Most loss
is directly at the base of the vertical. Plant a lot of radials lining
the garden, and you will do ok. MK

Hi Jim,

OK, you disagree, but with what? Scaling will ALWAYS answer
everything but the mystical apologies.

>
>Most important to me is that the antenna offers no real advantages

This is more pilot error than design error (which has its own
problems, of course).

>And again - what advantages does it have over, say, a W3DZZ trap
>dipole?

I see no such issues if the theory were hammered out. It is plainly
these readings of tea leaves that frustrate construction, because when
a design is described, it is most clear and concise - it just doesn't
work is all.

Like I said, I've done some measures and added a dozen more since.
The results are interesting. I can come up with a four band antenna
without too much trouble; however, getting those bands into Ham
regions (all of them) is another matter. I can do this with a simple
run of twin lead, and one strategically placed short between them.

This antenna (usefully resonant or otherwise) is no worse than any
wire strung between poles - just two wires instead of one, hardly what
I would call fragile. If it has an advantage over your W3DZZ trap
dipole, I leave that strictly in the eye of the beholder as I have
full faith it won't be any worse.

Any way, such work offers a step towards an antenna with MORE gain
(and more wire, a third one) by constructing a Franklin Array style of

antenna. True, not a multi bander, but I am not particularly nailed to the floor over that.

FYI as any one reading this can guess WA3MOJ, is being forged.. It is being done by a group of anonymous out law CBers from rec.radio.cb. Thier goal is to punish licensed hams who have spoken out against freeband, mod'ed radios, and, illegal power in that newsgroup. Operating outside the rules means a lot to these CBers. Anyone that disaproves of it is seen as a threat. A licensed ham who does not 'go along with the program" and is foolish enough to use his callsign in that group gets harrased. Recently, one, of the out law CBers rang door bells, left notes, and took photos at the residences of hams N8WWM and KC8LDO for the purpose of stalking them. This is now a court matter. Also these same CB out laws are so ignorant they get mixed up and latch on to call signs of hams who do not even post there which is the case with WA3MOJ, N7VCF, and, others. It may be best to let them forge away so that the ISPs involved can shut them down.

Source record: 96315

Hi Richard,

My beginner's understanding is that I would have a better multi-band antenna utilizing a balanced feedline than with coax. I had seen a couple of recommendations by doing internet searches. Several operators spoke highly of the ~540' loop with balanced feed. I have a nice old 250W Johnson matchbox on hand. Again, my beginner's understanding, the more wire=the better, so I figured this long loop would be a good antenna for "all" bands.

I am just now setting up a station for the first time. I need to think I know what I am doing long enough to simply put something into action for fear I will spend forever in a complex endless decision making matrix. I enjoy trips to the hardware store and the junkyard, I haven't even been on the air yet......(or at least since 1953....).

I figure antenna concerns are first, a good ground, then I need to think about some serious equipment. This can be a bit overwhelming. Ihis next Sat. I will be going to a local hamfest (my first one), hopefully to meet some locals and make friends (mentor's, Elmers, etc.), also to track down the guy with the bow and arrow who can get a line up my Eucalyptus tree (165'+) for another possible antenna in an alternate shack on the property......

actually, now that I think of it, my whole involvement in ham radio at this moment (besides the fun of studying for the exams last month) is dreaming of antenna farm.

just the other night while listening to some local maniacs on 3840, now I realize I need to get my Extra if I want to be able to chime in at that frequency.....those guys last night almost shattered my naive expectation that hams are always gentlmen, a pursuit of integrity I personaly fully intend to promote in my own operating demeanor. Apparently there is some "famous" AM talk show host involved with that little late night net..... shame on them....

Great, now I have a shopping mission.....go out and buy the Extra exam book.....I do actually enjoy studying and learning.....

Now....a trip to the junk yard to find an old fashion DPDT Knife switch I can mount on the wall so I can switch my incoming balanced line from the Johnson to the Kenwood tuner....

help!.....

Hi Cecil,

I will check that out.

While playing around with wire last night, seriously, the diy that looked like it would work best was the sample I put together with some #10 bare copper!

I have been known to end up doing things the hard way, and overdoing things....

so why not this #10 bare copper ladder line?

73,

Bill

Hi Irv,

The 300 ohm TV line I am sure works, but it does not appeal to my tendency to want to make everything "industrial strength" as if we were all going to live for ever. I am finding it difficult at the moment to resist the idea of making my ladder line out of #10 bare copper, thus insuring I will have a *&^%$#@!!!!! time up on top of a ladder yelling and screaming things like ("why do I always make things so difficult) hi hi. Actually I think that the #10 bare copper ladder line with my secret hardware store insight spacers will look impressive.... (who am I trying to impress is the question) I need to get my butt on the air otherwise I be only a "theoretical" ham.....

Secret hardware store spacer insight: the 4" uv/pvc ferrules that come with the gutter spikes!....no I didn't say gutter snipes.....hi

73

everyone was working this guy in Lithuania on 20m this morning....can't wait to get in there..... fun.....

Hi Mark,

Thanks for the response. Good, I won't worry about it. But I do know about coax seal, rubberized electricians tape, and being throrough with my connections.

tnx agn.

"Tilt" is very good advice for a variable mercury column.
In fact, the tuning length of the column of mercury could
be controlled simply by tilting the tube of mercury at an
angle away from vertical in the direction of horizontal.

Precipitation in general, and snow in particular, can have another effect on the antenna. And that is static buildup. You can get static voltages large enough to damage sensitive semiconductors, such as MOS transistors. It is usually recommended that you have the antenna either DC grounded or have some type of sparc gap for the static to jump across. Of course, your antennas should be grounded when not in use but not everyone does this.

In the winter, don't forget, you can get ice buildup on your antenna and feedline

From personal experience---I was a memebe of the radio club at Ohio State (W8LT) many years ago when they were located in the OSU stadium. We had a genuine long wire run from the stadium over to a smoke stack on the power plant it was a few hundred feet long. In the winter when ever we had a dry snow there would be quite a static build up. There was a sparc gap inside the antenna tuner, and you could hear it going snap snap snap as the charge would build up and then arc over. I certainly wouldn't want to get my fingers across the thing under those conditions.

Well, after I replied to you post I remembered another antenna type. The reason I mentioned the Turnstile first is that it is easier to build. You are right. The pattern does fall apart when you get into the same horizontal plane as the antenna.

You have two choices. Either a highly directional antenna, for which you would have to have a tracking system to follow the satellite, and the appropriate software to run the thing (predicting when and where the bird will appear).

The other choice, which is what I would recommend, is the quadrifilar helix. It can be designed to have a hemispherical 180 degree beamwidth and still have the same RHCP over entire beam. I would even suggest making it a bit more than 180 degrees beamwidth, perhaps 200 degrees. The problem with the quadrifilar helix is that it is harder to build than a simple turnstile, but still easier than a directional antenna with two axis directional control. A Google search gave 2860 hits for "quadrifilar helix". One I looked at was http://web.ukonline.co.uk/phqfh/qfh.pdf . If you are not afraid of the metric system, it gives detailed construction notes for a 137 MHz antenna made from copper plumbing parts.

With a fine enough ground spacing, though, I would think that the path is
'direct enough?'

I thought the entire point of the ground plane was that the induced currents
are necessary to make up for the current sources that are 'supposed' to have
come from the 'missing' half of the antenna?

Hi Richard

Thanks for the advice!

However, I do use copper radials from each vertical.
From my Butternut HF9Vw/160 I used 3,500 feet of copper wire to make the radial bed. These were tied to an 8 foot grounding stake and connected to the antenna's grounded mast.

I have antennas that did not work well at all when placed in the front or side yard, but worked quite well in the back yard over all of that mesh of buried wire!

Because of this, I'm planning on trying to duplicate as closely as possible, what I had that worked so well for the last 20 years.

Hi Zeno

Some will say it don't affect it all, others will say it will affect
it a little bit and other will say it affects it alot.

I had several little 1/16th watt neon lights laying around doing
nothing. I would toy with them, lining them on dipoles to find the
highest area of RF on the dipoles, once found, I would solder these
little rascals to the dipole so they wouldn't move in the wind.

Besides looking cute, they offered a little bit of help too.
When it was raining, they wouldn't lite at all on a couple of
antennas, and on others were very dim.
This alone tells me that there is some affect of rain on the antennas.

But one question has always perplexed me to no end.
Why will the light light up if placed on the end of my 10 meter mobile
antenna, but not on the end of 10 meter ground plane. It lights up
just fine about 19 inches below the top on the ground plane and about
22 inches below the top on a vertical with an underground radial bed.

There's something called an EH-antenna... despite many claims it is not a wonder antenna, but it does get you on the air... it's not a substitute for a dipole or beam though (I saw a 160m 2 element quad.. that was a monster, but I digress).

www.eh-antenna.com

Somewhere I saw someone's test of one at some low band... 80 or 160m I forget which... It was pretty good sized, but tiny compared to say, a dipole. 2-3' in diameter, looked to be about 10-15' tall. no real good 'scale' photos.

I have seen a couple of 'how to build' articles on the web, but don't have them handy I'm afraid.

Unfortunately nothing is going to work really well... given your space limitations. I'd go for as much of a vertical as I could, and run ground radials in the garden, or maybe a <ehem> 'long' wire run around two sides of the property maybe?

I've heard rain affects balanced line, but I use standard insulated
450 ohm ladderline to feed a dipole, and I can't detect any SWR
changes when the line is wet or dry.

At the higher frequencies, one way to make a 50 Ohm antenna is to arrange it
as a full wave loop, but make it about twice as high as wide. That is, you
end up with an antenna that is 1/3 wavelength high, and 1/6 wavelength wide.
It's a balanced antenna, so you don't need ground, but the whole thing has
to be well up in the air.

Guys and gals,

I'm working on assembling a groundplane antenna for my truck and am wondering what materials to use. I know copper is likely the best, but since I've got 1/8th inch steel rods laying around, I was wondering if I could use those for the ground radials? I'm using the whip off an old magmount for the transmitting element, but that's all of that material I have handy. I'm not terribly concerned with the rust as I plan on painting the whole assembly anyway.

I'm sure I can get some aluminum rod or brass/bronze rod at a local welding shop if they would be better materials, rf wise.

Joel Kolstad wrote:
"I thought the entire point of the ground plane was that the induced currents are necessary to make up for the current sources that are supposed to have come from the "missing" half of the antenna?"

The currents need to be induced in low-loss material for efficiency.

The performance is as if a vertical and its reflection made up a dipole in place of a monopole and its reflection. The equivalence is very good in most respects.

According to Laport, G.H. Brown, the inventor of the "ground plane antenna" and one of the famous "Brown, Lewis, and Epstein Trio" at RCA is responsible for using electrostatic principles for describing a ground or image plane and writing the equations to quantify the potentials due to the charges on a system of cylindrical conductors to be used as in a transmission line to determine characteristic impedance in terms of capacitance per unit length and the velocity of propagation of a TEM wave. See page 513 of "Radio Antenna Engineering" for details.

A vertical radiator driven against the earth or a ground plane needs to complete its electrical circuit between the radiator and ground through existing capacitance via capacitive (displacement) current. To minimize loss, ground current in the lossy earth is minimized by using enough radials of sufficient length to capture nearly all displacement current before it can flow through any significant length of earth.

If the vertical radiator is high above the earth and far away from ground, only a few radials suffice to capture nearly all displacement current. Earth far below is out of the current loop.

When the radials are near the surface of the earth, many radials are needed to hide the earth`s surface from displacement current with the vertical radiator. Fortunately, when the radials are closely spaced, any current induced in the earth doesn`t usually travel any significant distance before being collected by a nearby radial and this keeps the earth-current loss down. For the FCC, 120 radials of 1/4-wavelength evenly distributed around a 1/4-wave vertical radiator are just about perfect for the medium wave broadcast band.

Some of B, L.& E.`s performance charts are on page 119 of "Radio Antenna Engineering".

Best regards, Richard Harrison, KB5WZI

Understood, Cecil, but when the SWR losses are of so little concern
then the SWR consistency becomes likewise, at least IMHO.

1184. Transmission line radiation

Newsgroup: rec.radio.amateur.antenna
Date: 2004-04-20 21:39:16 UTC
From: Ron <rmrippy@hotmail.com>
Message-ID: <8Mghc.25538$6m4.1042660@twister.southeast.rr.com>
Source record: 96234

Can someone explain how a transmission line starts radiating as the separation between the center conductor and ground plane becomes greater and greater. Assume you out start with a wire over an infinite copper ground plane that forms a 50 ohm Zo transmission line. Then increase the distance between the wire and the ground plane until the wire becomes an end fed antenna. What happens to cause radiation to begin?

Ron

>I'm working on assembling a groundplane antenna for my truck

Hi Jeremy, I guess you are assembling a mobile antenna for your truck. The groundplane for it can be the metal body of the truck. No need to provide "ground radials", although a groundplane at VHF, mounted on a truck has been spotted by some folks.
Just use a simple 1/4 wavelength whip at the transmitting frequency, connect that to the center conductor of your coax, and securely bond the coax shield to the metal body of the truck. I would not paint. The mounting details are usually the most difficult.

You can use any material that will conduct . The main thing to look at is will it stand up and be mechanically sound. While you could use 1/4 inch copper rod, if it is more than about 6 inches long it would bend out of shape with a small ammount of wind.

Jeremy, KC5TEK wrote:
"I`m not terribly concerned with rust as I plan on painting the whole assembly anyway."

My 2-meter groundplane uses a GM telescoping car antenna as a radiator and steel shelf-support channel from Home Depot as radials. These are solid rust after many years and they still work fine.

Groundplanes are best for fixed locations unless you are using a vehicle body or the like for your groundplane in a mobile application.

Commercially, the simple whip antenna worked against a car body has almost universal acceptance.

For workboats to get a little height for greater line-of-sight we used coaxial antennas. The vertical whip was half a diploe. A brass tube skirt served as the other 1/4-wave part of the vertical dipole. It could be elevated as high as convenient and worked as well as a groundplane but with no risk of poking out an eye on a tossing and turning boat. My ARRL Antenna Book has no construction article for the coaxial antenna. I wonder why?

Best regards, Richard Harrison, KB5WZI

Ron, A transmission line, by definition does not have a center conductor, and a ground plane that it reacts with. A transmission line is two close parallel conductors carrying equal current, but 180 out of phase, so the EM fields created by each conductor cancels. A transmission line does not radiate. If you start increasing the spacing between the conductors, then the EM fields cannot cancel, and according to Maxwell and others, radiation occurs, you have an antenna. The most efficient radiator is a 1/2 wave dipole, almost 100%.

>use a glass tube.

Hi Steve,

It doesn't work that way. The mercury will create its own void -
thing called gravity and the pressure of the atmosphere around us are
in competition (even if the tube is sealed). Fill it to absolute
capacity (no reservoir) and you will either pop the tube (thing called
thermal expansion) or draw a vacuum.

Pressure, gravity, temperature - all things mercury is sensitive to.
It would be easier to herd cats.

Source record: 96247

Ron, when the conductors in a transmission line are close, much much less than a wavelength, the currents, which are out of phase, create plus and minus EM fields that effectively cancel in all directions.

As the spacing becomes greater and becomes a significant portion of a wavelength, the fields cancel in some directions but the spacing causes the phase to add in other directions. Under this class of conditions the line starts to become more like an antenna than a transmission line.

As a point of further confusion, coaxial cables that have woven overbraid have a leakage inductance that allows some of the rf to leak out. So, even coax has some radiation due to leakage.

Hi Ron,

How it starts? You left the hose running. It comes out the end
because there is nothing there to keep it in.

This is not to say it comes out with a gush, however. A very short
protrusion of wire (the teensy radiator above this ground plane) has a
very, very small radiation resistance. In comparison to its Ohmic
loss, it can be so short that the wire itself simply turns it to heat
(or reflects the power back to the source due to the massive
mismatch). Result, not much gets out.

Increase the length of the wire, and the radiation resistance rises
faster than the Ohmic loss (the whole point of radiation is to load it
into THIS resistance and not the Ohmic loss of the copper). There may
still be a mismatch, but with the Standing Waves residing along the
length of the wire (now of sufficient length so that radiation
resistance dominates) the power eventually (within microseconds) gets
radiated. Result, enough gets out.

Increase the length of wire to wavelength proportions (typically a
quarter or more), and the radiation resistance easily eclipses Ohmic
loss. Result, most of the power is transferred out.

Let's fantasize some numbers:
1 inch radiator offers 0.001 Ohm loss and 0.000001 Ohm radiation
resistance. If you could tune this mismatch, you've got yourself a
cigar lighter. At night, folks would see you before they could hear
you.
1 foot radiator offers 0.01 Ohm loss and 0.0001 Ohm radiation
resistance. If you could tune this mismatch, you've got yourself an
infrared lightstick. You might be heard AND seen at the same
distance.
10 foot radiator offers 0.1 Ohm loss and 0.1 Ohm radiation resistance.
If you could tune this mismatch, you've got yourself a baseboard

heater suitable for a mobile 80M shoot-out.
100 foot radiator offers 1 Ohm loss and 30 Ohms radiation resistance.
Now you are talking DX.
Caution, these numbers are spun from whole cloth, but it illustrates
how important the relationships are.

Length counts in relation to wavelength. To strain a metaphor, how
warm and comfy would you feel on a cold winter night with an electric
blanket with a one inch element? Increase the length, spread the
load, and the best purpose is achieved with both.

Good sites.

Some may wonder why there are different geometries for the 'same' antenna'. The reason is that the quadrifilar helix can be designed for practically any beamwidth up to 300 degrees or so. This results in different lengths and number of turns. Some designs are open at the bottom and some are closed at the bottom. It all depends on what you want the antenna to do.

The funny thing is I actually got this Spam in my email the day after aquiring a 250 Watt Johnson Matchbox exactly when I was wondering if I should have got the 1000 Watt instead. The spam said "Is your johnson big enough?" and I wondered how the heck did they knew I was thinking about that. Turns out the spam had nothing to do with ham radio, wink wink, nudge nudge, know what I mean?

Only thing is the KW Johnson is rather inflated pricewise these days. I am trying to stay within a budget. I understand that since the 250 Watt Johnson was used for AM that it could probably handle 600 Watts of SSB or even CW, this is what I have seen posted by perusing through Google searches. What are the limits powerwise of this smaller Matchbox? If I want to think about a linear amp, I may want to know my limitations with the smaller matchbox. Are linears such that you "select" how much power, so even if the linear is capable of more than the matchbox, I could experiment to see how much the matchbox would handle. I apologize for all these newbie questions. Maybe a Collins 30L-1 would be a good companion to the matchbox...

According to Kraus' "Antennas" 92nd edition, chapter 2)....

An electric charge traveling at a uniform radiation along a straight wire
does not radiate.

When the charge reaches the end of a wire and reverse direction, it
undergoes acceleration (and deceleration) and radiates.

AN electric charge moving at uniform velocity along a curved or bent wire
is 'accelerated' and radiates.

An electric charge moving back and forth in simple harmonic motion (that is,
sine wave) has periodic acceleration and radiates.

If you have two parallel wires, one carrying a positive charge and the other
carrying a negative charge, it will not radiate.

If the two wires are bent away from each other, the charges radiate.

Kraus goes into more detail on all of this. Get yourself a copy of the book
or find one at the library. If they do not have one, they can get one on
interlibrary loan.

Some (biased) experiments have been performed with twinlead laying
on a wooden deck wetted by a soapy solution. Moral: Avoid soapy
horizontal ladder-line. :-)

I use the length of the ladder-line to tune my antenna system to
resonance. I have to change the length by up to 2% to compensate
for the rain, i.e. rain has a negligible effect on the tuning of
my antenna system.

> end fed antenna. What happens to cause radiation to begin?

Electrons shed excess energy by emitting photons. If those
photons are absorbed by electrons, they don't radiate. If
they are not absorbed, they radiate (at the speed of light).
This is one area where quantum electrodynamics is actually
easier to understand, from a conceptual standpoint, than
Maxwell's equations.

> Point/Counterpoint.

If the SWR on 300 ohm twinlead is 5:1, the impedance at the current
maximum point is 60 ohms. If the SWR on 300 ohm line is 20:1, the
impedance at the current maximum point is 150 ohms (3:1 SWR).

If the SWR on 600 ohm line is 10:1, the impedance at the current
maximum point is 60 ohms NO MATTER WHAT THE ANTENNA IMPEDANCE.
The impedance at the current maximum point for a 6000 ohm antenna
fed with 600 ohm line is the same as the impedance at the current
maximum point for a 60 ohm antenna fed with 600 ohm line. That's
a definite '+' in my book. I like 60 ohms better than 150 ohms.

The requirement for the radials in the case shown at
the URL is because the antenna is elevated and
designed for hitting satellites. For normal low angle radiation a simple
magmount using the vehicle body as a groundplane would work.

Jeremy,
The 'radials' aren't really necessary if you mount the
antenna directly to the vehicle's body (metal car body is
the ground). The whole point of the antenna at the URL
is that he didn't want to drill any holes in his vehicle.
If that bothers you too, then follow the directions.
The rods you have will probably work as well as anything
else you can find. The difference in conductivity between
your rods and copper just isn't worth worrying about. The
difference in durability ~is~ worth worrying about!
Have fun...
'Doc

Kathy, I lived in Shorewood, Excelsior, Chanhassen, and Orono. Non of
those
towns have restrictions that I knew of.
Only new developments will have restrictions. The older communities
never had them and porbably won't.
You can find really nice wooded properties out in the western
suburbs, with good antenna trees. Orono would be a good place to
look.

A slightly different way of looking at it from what Gary wrote...but
quite similar.

It's better to think of a two-wire transmission line, probably. If
you want to think of the ground plane, just realize that it's
identical to the situation with two conductors driven out of phase:
you can insert the ground plane without any effect on the fields at
all.

Then each wire does radiate, but to the extent that their currents are
coincident in space and in opposite directions, those radiations
cancel. Net field at any point in space is the linear combination of
all the fields arriving at that point, at that instant in time. As
the wires become more separated, the radiations observed at a distance
no longer cancel. You're not the same distance from each wire, and
more importantly, the phase you see differs. Consider what you see if
the wires are separated by half a wavelength, and you are in the plane
the wires are in...and what you see if you are in a plane
perpendicular to the plane the wires are in and passing between them.
If you observe the fields close to one of the wires, of course the
cancellation is not good there, either, though that's energy
propagating in the direction of the line. Note that there's no
radiation from coaxial line, so long as the net currents in the inner
and outer are exactly out of phase and the current distribution is
uniform around the outer conductor (assuming the conductors are
exactly coaxial), even if the outer conductor is not very thick.

I'll (once again) recommend the "Antennas" chapter of King, Mimno and
Wing, "Transmission Lines, Antennas and Waveguides." You'll find it
in the antennas chapter rather than the transmission lines chapter
because it's radiation rather than energy propagation along the line,
I suppose. The introductory material in that chapter bears on this
topic, and later in the chapter there's very specific mention of
radiation from transmission lines, including what seem some
non-intuitive results about amount of radiation versus line length.

Cheers,
Tom

With two antennas in phase you can steer the null by moving the
horizontal spacing of the antennas. This was commonly done in cable tv
head end reception some years ago where there would be an inter
fearing station close in azimuth to the wanted station.

S search may yield the formulas for the distance verses the degrees
off null.

That's an interesting one I'll remember.

However, the idea is to make an unbalanced antenna with all the elements
connected to ground. The folded monopole is an excellent example.

Thanks.

Source record: 96122

Hi Cecil,

The only reason I was considering #10 solid wire was because it would absolutely hold its shape with a minimum of spacers. Aside from the fact that it is electrically overkill, you are saying that even wire that thick could possible flex enough over time to fatique and fail? Somehow I got it into my head that the best way to go was homebrew ladder line, and the only way I could see doing it myself was with this thick wire, all other wires were too messy somehow.

I checked the #554 that you suggested and it is rated for full power. I didn't realize that #14 wire could handle that (guess I have AC wiring in mind and not RF). So you have come to the conclusion that this wire is the best way to go for balanced feed line all things considered? (weather, dirt, etc.) Maybe I should just use that and move on from this obsession about making my own ladder line. I'll tell you that #10 was going to look cool in a kind of science fiction movie laboratory kind of way..... It is hard to get off that track, but maybe I am not being very practical...

I see that Radio Works also has this #14 copper-clad for about the same price, he says that the actual impedance is approx. 390 ohms.

Now I am wondering how I got onto this do it yourself homebrew ladder line obsession in the first place, I think it was some folks complaining about how erratic it was with the rainy weather and when it gets dirty, and stories of oldtimers going out and coating it with bacon fat etc. yuk.....

So you are predicting eventual unhappiness with #10 bare copper wire ladder line with cute little gutter spike uv/pvc ferrules as spacers. Why do all those guys make their own ladder line...is it because the commercial version is nearly 30 cents a foot? Or is there some other downside they were trying to avoid?

I was going to order some stuff from Radio Works anyway, so I could just get a chunk of that #14 ladder line......unless ....

Zeno (can't seem to really get away from this nickname....so maybe Bill will just have to wait in the wings.....)

>are the limits powerwise of this smaller Matchbox?

That's going to depend to some extent on the characteristics of the load. Very low, very high, or very reactive loads can be difficult for a tuner to handle - they can result in high voltages (the capacitors or the output connectors may arc over) and/or high circulating currents (high losses in the inductor, leading to heating). A tuner might misbehave into some loads, at power levels where it'd have no difficulty at all into easier loads.

> Are linears such that
>you "select" how much power, so even if the linear is capable
>of more than the matchbox, I could experiment to see how much
>the matchbox would handle.

Depends on the design. Some may have adjustable gain, some may have an adjustable input attenuator. Others are fixed-gain and you'd need to reduce the RF power output from your exciter/transmitter in order to make a proportional reduction in the linear's power output.

Hi Richard,

You remind me that I do not understand something. Let's say the characteristic impedance of this 540' loop is in the neighborhood of 140 ohms in free space, or even as you say closer to even 35 ohms in reality. Your point was, if I understand correctly, that this is in the ballpark of 50ohm coax and you suggest it can just as easily be fed into the coax.

But I thought that coax is unbalanced and the point was to go with a balanced feed line?

I guess I am not understanding the relevant differences between balanced vs. unbalanced feedlines, and getting the impedance of the the transmission line close to the impedance of the antenna.

I thought the point of my striving to use balanced ladder line was to somehow gain something that would be compromised by using coax. I thought that the the ladder line which might be 488 ohms say is still going to be a better feedline than using the 50ohm coax. The coax would still then require a balun, correct? (a 1:1 banlun?).

It is sites like this: http://www.cebik.com/par.html that tend to get one thinking about this whole diy approach.

My reading and gleaning of websites has me of the opinion (at this point) that the balanced line with this long loop is better (multi band) than to feed it with coax.

I believe Cecil has already explained this in terms of the wide range of actual resistance that may be encountered multi band. (hey, I am just now learning to talk this lingo....just barely know what I am talking about....operating intuitively, and with the kindness of strangers.....

Zeno (aka Bill) KG6UHM for the moment.....

Not the best, but hard to beat for the price and convenience.

> So you are predicting eventual unhappiness with #10 bare copper wire
> ladder line ...

The solid copper wire usually breaks at the antenna where there
is lots of lateral movement. That can probably be cured by a
rigid center support.

How much gain do you need? The quadrafilar is low gain, and the helical beam
is high gain, but you have to point it.
Check with the weatherfax sites, they should be close

Hi Bill,

True, but easily answered with a feed line choke (1:1 BalUn) at the
drive point that will render the coax balanced if the load is - being
that close to ground there is every chance that may be debatable.
Again, there is no getting it right the first time out of the box -
you can only put it up and test to see how much you need to change it.

You were planning pulleys right?

>I guess I am not understanding the relevant differences between balanced
>vs. unbalanced feedlines, and getting the impedance of the the
>transmission line close to the impedance of the antenna.

You can build a twin line of 50 Ohms. Takes pretty close spacers, and
you will need a lot if you use bare wire. The wire pairs would be as
close as zip cord. Twisted pair, insulated could do the trick (might
even match the 35 Ohms).

>I thought the point of my striving to use balanced ladder line was to
>somehow gain something that would be compromised by using coax. I thought
>that the the ladder line which might be 488 ohms say is still going to be
>a better feedline than using the 50ohm coax.

Well.... Only if you use this as a monobander. As a multibander it
will ALWAYS have SWR, the point of big wire twin lead is that the loss
will be less than if you used the same antenna with coax feeding it.
Coax with big center wire is HUGE and COSTLY for the same loss figures
at the same SWRs met by multiband use.

For 160M band, I would REALLY look for the Archer and put my effort
into that prospect. A low loop is the pits - hi Z, lo Z, balanced,
unbalanced, SWR, no SWR hardly counts for diddly.

>The coax would still then
>require a balun, correct? (a 1:1 banlun?).

ibid.

>It is sites like this: http://www.cebik.com/par.html that tend to get

>
>My reading and gleaning of websites has me of the opinion (at this point)
>that the balanced line with this long loop is better (multi band) than to
>feed it with coax.

True enough. I simply responded to you describing it as a 160M loop.
If it was a dedicated monobander, twin lead is extravagant and forces
unnecessary SWR into the picture.

>I believe Cecil has already explained this in terms of the wide range of

Actually, i think this might be an interesting experiment.

I would assume the neon lights have a brightness that is proportional
to the RMS voltage, and that the areas of brightest neons are high voltage
(low current) nodes.

One question is how are you hooking them up? On the dipole?

S.

Here's a helpful hint on the (ohmic) loss: what is the power rating of the resistor (and is it wirewound?) and what is the rated input power at the feed?

Obviously there are multiple current maxima at the high end of HF That would seem to count for something:-)

Graph the mismatch loss vs ohmic loss over the entire passband, then plot the peak gain compared to a (dipole of the same total height)--and then tell us this antenna doesn't work:-)

Key question: what problem was this antenna solving? I bet that a 110 ft inverted V--unterminated and ungrounded --was far worse in solving the problem as posed.

Tnx for the reply, Danny. Yes, their support is very good and generally a pleasure to have dealings with. I just figured there was a pretty good user base established for that rig and some folks had some favorites for mics. I use an old TS 520S here with a modified D104 lollypop that works like a champ but even though I know several people using the Heil mics on them, I don't like the sound as well as the Astatic. By the same token, I've a KWM2a here that sounds superb with the HHG mic by Heil. I suppose much of it is personal preference after all, but if the Omni D is like any other radio I know there are some landmines that would be best avoided and that's what I was looking for.

73 and good DX!

Paul,

Very true. However, how it *sounds* is somewhat subjective as it
depends upon personal preferences. I have a TenTec Paragon that I am
using with an old Kenwood MC-50 microphone and have been satisfied,
but that is because no one has given me a poor report on my audio. <G>

Good luck,

Danny, K6MHE

Would these work, or am I crazy? I would also entertain the idea of both being crazy and the ideas working ;-)

Take a normal 146 MHz quarter wave mobile antenna and heat shrink a piece of insulated wire to it. The wire would be a half wavelength., more or less, at 446 MHz. Trim the wire for minimum SWR at 446 MHz.

Another idea. Take a 446 MHz quarter wave wire with one end uninsulated. With the uninsulated end up, attach it to the 146 MHz quarter wave with heat shrink. Adjust the position and length of the quarter wave wire for minimum SWR at 446 MHz.

Bill wrote:
"What is the general effect of moisture on antennas and feedlines as power is increased?"

I worked for years in a shortwave broadcasting plant where transmitters ranged in power between 3KW and 100 KW. Moisture had little apparent effect on the 600-ohm open-wire feedlines or curtain and rhombic antennas at any power level.

We can speculate that wet insulators were slightly conductive when wet due to disolved impurities. Ohm`s law says current and heat are higher at high power.

The climate was dry for most of the year but the rainy season was intense resulting in occasional floods. As I recall, transmission line flashovers rarely happened in wet weather but dry was the norm and arcs were infrequent in any case even at 100 KW with 100% high-level modulation.

From my mediumwave experience I would say that most antenna system arcing resulted from approaching moisture, not to its arrival.

Approaching thunderstorms are often preceded by charged air sweeping across the antenna system. Tower guy segments, separated by insulators, charge until they arc across the insulators with a loud report (Bang!). This triggers ionized paths which short antenna system parts. This overloads the transmitter which removes itself from the air to clear the overload and protect itself. This often repeats rapidly until the storm actually arrives and the rain starts.

Best regards, Richard Harrison, KB5WZI

Message-ID: <c662pe$8gu1d$1@ID-225206.news.uni-berlin.de>
Source record: 96147

Idea 1, would probably not work much at 446 as current would have a hard time to flow into attached insulated wire. general problem with most mobile antennas is getting enough RF current to flow out into them.

Idea 2, May almost work, as the 446 is almost the third harmonic of 146 and the antenna would be resonant again, 438 is 3*146 only a 2% change, close enough to try it once. Bandwidth of antenna is the critical factor, tune for 3/4 antenna of 446 first and then see where it came out near the 146. Then split the difference between the two, a sweep of return loss would show you the antenna bandwidths, and if it is possible, If no go, try Idea #3

Idea 3, Other cases -- use a dual ban antenna approach, put a loading coil in the middle (airspace turns), the bottom part is the 446 1/4 wave, and doesn't "see" the top part due to the coil. Then the full length with loading coil is equivalent to a loaded 1/4 wave at 146. Start with a 146 and center loading coil to shorten the 146 lengthwise. Then tune the lower rod for 446, so the coil may not end up in the center, but it will be right on on both frequencies. (should not take much of a coil since it is only 2% off) I did a triband one time with two loading coils for Low Band, VHF and UHF. Had a splitter designed to split off to the three radios in the trunk too.

Crazy ideas get patented!

Just got back from D.C yesterday to have my neighbor come up and tell me that my tower almost fell over Sunday during heavy rain and wind storm. He was able to secure the tower to the upstairs sun deck. What has me wondering is, the foundation that the tower sits on, sits about 2 inches below the cement porch which sits about 4 inches above the top soil. Now, the tower foundation sits an inch higher than the deck. I loosened the tie downs for the tower and I can move the tower and foundation. It almost looks like the foundation broke half way down because of the way it "pivots" on top of the broken lower half of the foundation. Looks like I may have to take the tower down this weekend and dig up the old foundation and see what happened. Neighbor said we had alot of rain in a short period of time. It's a good thing I had disconnected the 2 radios from the feedlines, cause, if that tower would have come down, it would have pulled both radios out of the window. ie, Icom 2100 and Icom 706.

Jim

You've got the concept. There is little lattitude for designing for Gain.
I do wonder how (if) there is a way to build an antenna that has RHCP
principally in the North and South sectors. It occurres to me that the
polar satellites will be approaching from "pretty much North or South".
And the passes that are far to the East or West are within range for too
short a time to be of value. So, I wonder if it would be practical to build
an antenna that has decent RHCP North and South. and overhead, with little
sensitivity East and West.
I have just about given up hope that I can design an antenna for this
'spec'.

Since I'm a poor reader, I'm not confidant I fully understand your objective. But, a folded monopole (1/4 wave) with a very fat "fed" element and a very thin "grounded" element, with very close spacing will have an input impedance lower that 150 ohms at *resonance*. It occurrs to me that you already know that.

Jerry.

I am going to meet the archer this weekend at the hamfest in Sonoma. Another friend is giving me a homebuilt house trailer (quaint gypsy wagon) which I can park out in the back 40 as an alt. shack which will be close to the antenna up in the <200' Eucalyptus tree. It is not that I am particularly excited about 160m (although good to be able to operate there when necessary I guess), but HEIGHT is everything, right?

OK, the 540' loop will be up as high as I can get it with these telescoping masts, somewhere between 45-55 feet at each corner. How will this be for bands other than 160m (either with the Johnson or my Kenwood ATU (+current type balun)? As mentioned I have the real estate to try several antennas here. I am curious to find out how the loop will work. I only call it 160m because of the length of the wire. There were a handful of websites expressing enthusiasm about this antenna.

Another plan is some kind of antenna on a rotator. Any ideas of how to engineer some kind of beam (light-weight) or something similar atop one of these 50' telescoping tv masts? If I am to telescope 4 - ten foot sections, the antenna and rotator would have to be light. I would have to engineer this with a crew of buddies holding the guy ropes as the stong person is up ten feet trying to push up this whole thing into the air a section at a time. Anyone done this? The motivation here is 1) I have the 50 mast, so economy is a factor, and 2) the result will look more like some kind of elaborate tv antenna. A tower out in the front yard might be a bit much in the neighborhood at this point. I need to test these waters first.

Ok, so do you electrically attach the two leads together
make a loop out of them, and then wrap this loop around the
dipole? That's what the other poster seemed to be suggesting,
use an inductive pick-up loop, which essentially shorts the
two leads together (a DC short that is).

Hi Bill,

Above 80M it should be gangbusters. However, you may wish to look into Rhombic designs given the vast footprint available to you to experiment with. This will be more directional, more gain for the 30M bands and above, so you will want to investigate what direction that should be (don't guess using a flat map either). It would be roughly the same shape, only more diamond than haphazard square. Such a design shouldn't hurt your 160M loop prospects, but would optimize the higher bands (where formerly you were just going to take what came with the turf).

With a lot more wire (and work), you could get into the Fish Bone Array, or a wire Log Periodic Array. Both would, again, be fixed direction so planning ahead is again seen in the XTAL ball.

>I am curious to find out how the loop will work. I only call it 160m
>because of the length of the wire. There were a handful of websites

What choice did they have? Such is the fallacy of testimonial. As the saying goes, if all you have is a hammer, everything looks like a nail.

That would have to be WARC bands and 10M, probably; otherwise you are dreaming in technicolor and surround-sound.

Hi OM,

Cut the wires off - it doesn't matter, the energy is in the field and
THAT is what is lighting it up. [Standard lab demo of exciting an
ionized gas.] In the late 70s you would find these lamps at the end
of CB whips.

If there's 19+ inches under the coil, chop the coil off
and throw it away. If there's not 19 inches under the
coil, short the coil out and trim the entire antenna
length to 19+ inches. Leave enough for cutting and trying.

Hmmm.

Interesting idea. Almost said I would have to think on this, but one idea popped in my head as I was about to type it.

My idea is this. Build two (or more) quadifilar helix antennas. Each would have hemispherical RHCP overage. Place them on a line in exactly an east-west direction. Phase them properly and you should get a null to the east and west with 180 degree coverage north and south. The exact spacing that you would use is and how you would phase them is something that I would have to look up.

By Golly, I have been looking for a cable stretcher. A tilted
mercury column will perform that function. Question is, what
do I mix with the mercury column to make it more conductive?

Although I have the acres (7) there are a lot of buildings (old barns etc.), trees, etc. My antenna planning has to dodge many many obstacles actually. This is an old chicken ranch and there are building everywhere, then all the trees. Are you saying that a rhombic could be put up on the same masts more or less (only one of the masts is potentially moveable, meaning that it would only be diamond like at one end of the trapezoid. This rhombic would be instead of the 540' loop?

I will look up rhombic in the books and see what gives.

>

You're very perceptive, Jerry. How did you come to think I would know that?

You are correct, of course. The strange thing is that the graphs depicting that sort of behavior is not in the 18th edition of the ARRL Antenna Handbook (unless I somehow missed them) but they are in the 1977 edition of the Radio Amateur's Handbook. I had hoped to use a single wire formed into a hairpin for the sake of simplicity, but I am tempted to use the different sized conductors nevertheless. I have even chosen a ratio of 4:1 for the diameters.

Hmmmm. I wonder how it would work with, say, 1/2 by 1/16 inch metal bar and wire. Or maybe orient two bars of the same size 90 degrees (looking down the long dimension) so that the wide side of the "fat" part sees the narrow edge of the "thin" part. Like this:

```
.-.
| |
| | .-------.
| | | |
| | '-------'
| |
'-'
```

but connected across the top. Actually it could be made from one long bar with a twist at the top where the hairpin occurs. I don't know how to model that, so I'll have to build and try it.

The foremost objective is to learn. But, at the end of this particular quest I hope to wind up with a suitably rugged antenna mounted to the top of a remote data gathering device transmitting in the 70 cm band. The sensors will measure temperature, rainfall, soil conductivity, and anything else I

decide might be fun to know about. In fact, I plan to put another one down by the county road at the site where it floods. That remote sensor will tell me when the road goes under water so I can take an alternate route rather than having to back the car 1/4 mile to a turn-around spot.

So much to do, so little time.

Thanks for your reply.

John

Hi Bill,

No, this time shape matters as it is a function of all angles of
radiation combining to ADD rather than jumble. Again, think in terms
of the supports/mast merely being the outer, irregular perimeter to an
ordered interior antenna shape.

The Rhombic would BE the 540' loop. Normally it is open or terminated
at the end opposite the feed point, but having the shape anticipated
is more the work than this simple change. (It has the same feed
considerations, complete with your expected twin lead.)

Congrats on your desired call.

mobile
> antennas is getting enough RF current to flow out into them.
>

There are two ways that Idea 1 can be thought of:

A. The extra wire is a half wave dipole coupled to the 2 meter quarter wave. By some magic, it resonates and radiates on 446 MHz as a half wave dipole.

B. A shorted quarter wave transmission line is an open circuit. So is a half wave open circuit transmission line. The extra wire next to the 2 meter quarter wave acts like an open half wave transmission line, effectively isolating the upper part of the 2 meter quarter wave when operating on 446. When the wire is positioned properly, the bottom part of the 2 meter quarter wave will act like a 446 quarter wave.

The QFH scares me. I dont understand whats going on within the QFH
anrenna.

The 'actuallity' is; a turnstile antenna or a decent QFH is probably be
good enough. I guess I'd like to be able to contribute some thinking to
this "displaying weather pictures" poject.
I made one prototype turnstile and got marginal results. But the poor
signals were probably due to my building a faulty antenna.

I do have a book with a graph of Zin as a function of diameters and
spacing of the folded dipole. But, I dont have any equations. I suspect
someone on this news group has knowledge of where to get some math tools for
predicting the antenna impedance. I'd be glad to scan the page 16-6 of the
1990 ARRL Handbook for you if it would help.

> How so?

The gravity vector remains constant while the tilted mercury
vector varies with the angle of the tilt. Let's say theta
is the angle of the tilt, i.e. the angle between the mercury
column and the ground plane. At an angle of 45 degrees, the
mercury column length will be 1.414 times the length at 90 degrees,
At 10 degrees, the mercury column length will be 5.76 times the
length at 90 degrees. That sounds like something worth patenting.

You may or may not be able to easily use the antenna. It depends not only the radiator but also the base matching coil/capacitor. It would be easier and not all that expensive to use an actual 2m antenna, unless you just want to experiment. What you could do is get a 2m antenna tuner and hook it up to your existing antenna and see what happens.

73s,

Evan

Hi Jerry,

Odd, but one of the radio and antenna bibles of our group,
"Reflections," was written by Walter Maxwell who designed these QFHs
for the satellites - and yet no one has offered him as a resource or
reference. Try writing him at:
w2du@iag.net

The problem, as I see it, with using the fixed masts as outside perimeter configuration support structure for the specifically ordered interior shape is the sag the inevitably occurs when wire is a rope and pulley distance away from the supporting mast. I already see this with the tree supported antenna. The ropes drop down and the wire is 8' or so lower than anticipated. This seems critical when the masts are only 50' to begin with. How high, or shouls I say, what is the minimum height for an acceptable Rhombic?

Cecil, are you thinking of an open ended tube of Hg with a variable
supply of Hg?? My days with Hg manometers comes to mind.

If it's a closed tube then the length does not change with angle.

So, you can have your variable length antenna and not have it too!!

Deacon Dave

At my previous QTH I had a ROHN 25 at 47 feet length. The base was just under 2000# of concrete [approximately 4.5 feet deep to get below the frost line]. The three guy wire anchors were each 700-800#.

Held up fine in 80 mph winds.

Your base doesn't sound too solid. What were/are the base details?

I may be wrong, cuz I'm not very mechanical, but it seems to me
that a column of mercury in a tube with a vacuum at the top
and a reservoir of mercury at the bottom would change height
of column depending on the angle of the column's deviation from
vertical. It seems to me that when the column is horizontal,
there would be no vacuum at all in the tube.

It's probably been mentioned before, but there is a group that has
covered liquid antennas in great detail. See ->

http://groups.yahoo.com/group/Live-Wire/

Most of the liquid antennas are salt water based, but the idea is the same.

I have the exact antenna described on Idea # 3 ,, I have it on a magnetic mount, I use it for a bicycle, I have it magnetically mounted on a plate of steel on the back. I use it for 2m and 70cm, 2m SWR is flat and 70 SWR is very low, but I also use 156 megs a lot also. I was able to obtain a very low SWR on all three by folding metal tape in half like a flag at the bottom of the whip, about 2 inches up. 2 inch tape, tin foil tape for duct work (not duct tape) it is aluminum foil but about 6 mil and very tacky. I cut it to achieve a low SWR (about 6 inches length). So its like a metal flag, 2 inch by 6 inch length. Without it, I had very high SWR on the marine band.

Your 3 1/3 inches is only about 0.3% of the total length.
Whether the wire is insulated or not can make ten times
that amount of difference but you didn't tell us what kind
of wire you are using. Not only is it a nit, but it is a
negligible nit compared to other nits. :-)

>height for an acceptable Rhombic?

Hi Bill,

Think positively: how high will they be? 40 Feet? 10 Meters? One
quarter wave for 40M? This is not a hardship case. One half wave or
better high for 20M and above? No one's gonna let you cry in your
beer there either. And now for the classic "testimonial": it's gonna
be boomin! (what choice do you have?).

As a cautionary, don't try to pull out the catenary. The tension
rises with the tangent of the of the deflection angle. If you could
achieve perfect flatness, a breeze would snap the line.

It would do that, coupling would be 15 to 20 dB down though, and depends where it is located too. You could take the same piece and attach it to the other wire at the base and get the 15 to 20 dB back. (see Idea 1 A Modified)
You can cut the big rod for 146 and it will also pickup 446 both under 1.5 VSWR (says) so it is already a great antenna for 446.

Idea1A modified--Just have both rods come up out of the base (attached at bottom) bent away from each other about 25 degrees or so, one long and one short. (old time antennas did this one)
>
> B. A shorted quarter wave transmission line is an open circuit. So is a

> the 2 meter quarter wave will act like a 446 quarter wave.

It is the amount of coupling between the two upper parts may be low to lesson the effect. worth testing it, but you would need a different frequency, as the antenna already picks up both. But the preposed is 446 on bottom 1/4 resonate, and 1/2wave 446 on top next to rod, and rod could be at 120 MHz 1/4 wave length. The 1/2 wave may seem like open , but it probly does not have strong enough coupling onto the 120 Mhz rod to make it look open. (what if they are attached at that point, like a catus, 1/4 wave 466 up to attach point, 1/2 wave 466, and the rest of the 120 1/4 rod.-another

test? EZNEC!)

Cecil,

Could you clarify the dimensions of your column? Because the only portion of a cylinder of Hg that would lengthen is the tiny portion at the tip of the cylinder. Let's say the inner diameter of the tube was 1" (kind of thick for a tube of Hg, but makes for really easy math here... ;) If the column of Hg was 4'long by 1" diameter, tilting it to a 45 degree off vertical would only allow the volume residing at the very end to tilt (occupying 1" of cylinder length) and yes, it would (begging the question it had no surface tension) find level again and the bottom edge, effectively lengthening the metallic column by (1.414 * n) where 'n' is the affected volume. (roughly a length of column equal to the diameter of the column) Our 4' column would only lengthen to about 4' plus approx 1/2 an inch. The rest of the column is effectively captive to the inner dimensions (and volume) of the vessel containing it.

Bob.

I have used one for many years, right after it first came out. NO PROBLEMS. I have it on a telescoping TV mast. The bottom of it is about 20 feet up.

On 40 it is adjusted for CW portion, and use built-in AT in rigs for a match there.

Elsewhere it has acceptable SWR for each band.

With the idea that scaling answers all questions.

> Scaling will ALWAYS answer
> everything but the mystical apologies.

The two-band 80/40 dipole in the QST article has extra wires at the
junctions of the 80 and 40 sections because (according to the author)
the velocity factor of the tubular Twin Lead makes it necessary. Those
wires might or might not be required with a unity velocity factor.

In a perfect world, maybe. But in the real world of ham radio, most
hams have limited materials, test equipment, time and space. An
antenna made out of unobtainable materials, which requires
unobtainable tools and test equipment to build and adjust is only of
academic interest to a ham.

Exactly! If it cannot be easily duplicated by a ham with typical
resources, what good is it?

Which is not what Lattin did at all. Your design sounds far superior.
Is it on the web anywhere?

All depends on the wires. I use recycled #12 house wire, which stands
up under ice loading and high winds here in EPA. Yet it is hardly
noticed by the neighbors.

The main attraction of the Lattin is its claim to multiband operation.
Otherwise one might as well go with a plain dipole.

Possible Evan, I dont think it has a cap, I could easily get a 2 mtr and
mount it elsewhere, but I was hoping to keep the side mount of the CB as
it
matches the AM/FM on the other side.

Dont have a 2 tuner, but will play with it.

Thanks

Same here, have had mine up and going after fixing it last summer, went thru winter very well, not a sign of detoriation at all. Still works like a top. Now I don't know if anyone else did check the antenna with an antenna tuner (mfj 259 or whichever)
Did check mine out last year will doing the installation and found the antenna to resonant not to badly at all on 6 meters, and also on 80, where it would be a real compromise antenna. A bit hight on swr , but in a pinch i am sure it could be use with a tuner on at least 80 meters. Someday will check it out on the air on 80 meters to really find out what is what with it.

Just some feedback about R-7.

It is misleading to think that a feedline can radiate seperately from an antenna.

When a feedline becomes unbalanced with respect to an antenna it becomes PART of yet another antenna - which radiates.

The two TOGETHER form a resulting radiation pattern which is different to either.

I saw a further explanation in your later post. Important point - the resevoir, open to air or a source of constant pressure for example. As you tilt the vertical section, the height above ground remains constant because it is balanced by the pressure on the reservoir. In order to maintain the height above ground as the column is being tilted, the column must increase in length.

It works beautifully by the way, Cecil. I just tried it with a mercury barometer.

Source record: 96211

Scaling is a powerful analytical technique(*), but in some cases it can be a little trickier than meets the eye.

Consider, for example, scaling a piece of TV twinlead to twice the frequency so it'll behave exactly the same (both as a transmission line and as a radiator) at the new frequency.

The wire diameters have to be reduced by a factor of two.
The spacing between the wires has to be reduced by a factor of two.

Luckily, if the scale model and the original are both in free space, then

The dielectric constant of the insulator remains unchanged.

And, almost always overlooked,

The wire conductivity has to be increased by a factor of two.
The dielectric conductivity has to be increased by a factor of two.

Fortunately, these last factors are usually unimportant. If the original is made from copper, it isn't possible to scale to a much higher frequency. But it's something to be kept in mind if loss is significant and an accurate assessment of loss is necessary.

Permeability, incidentally, remains unchanged with frequency when scaling.

But even if you can neglect the conductivity scaling, you wouldn't be able to run down to the store and buy a piece of the scaled twinlead to use in your antenna for another band.

(*) Antennas are often scaled to higher frequencies for testing because the scale model is a more convenient size. When I was involved in the development of very high-speed sampling circuits, we often made scale models of various structures (for example, coax connector to microstrip transitions) at *lower* frequencies, so they'd be large enough to measure and physically adjust.

Robert Kole wrote:
"Put another way, should the overall length of the antenna be 102 feet or 102 ft. 3.33 in.?"

As Cecil noted, 3.33 in. is inconsequential in comparison with 102 ft. Your antenna has bandwidth, and 3.33in. is only 0.3% of its length. Given a tuner, the antenna system can be brought to resonance to remove a reactive impediment to antenna current and radiated power.

A resonant dipole system is 1/2 wavelength or some multiple thereof. It is a multiple of 180-degrees, tip to tip, and this includes loads, gaps, coils, capacitors, and everything electrically making up the length. See Chapter-8 "Dipole Antennas" in ON4UN`s "Low-Band DXing". Note that the tip to tip dimension includes the feedline spacing in all illustrations.

Bob, K5QWG referred to Cebik`s analysis of the G5RV, a 102-ft. version which is (3) 1/2-waves at 14.15 MHz. Note that Cebik also shows a 107-ft. version from the ARRL. Cebik notes that wire size and elevation are more important than wire length when you are using a tuner.

Best regards, Richard Harrison, KB5WZI

1312. Power cable routing, Ford Taurus

Newsgroup: rec.radio.amateur.antenna
Date: 2004-04-22 20:02:25 UTC

I am in the process of mounting my old Yaesu FT-4700 in my 2000 Ford Taurus station wagon. The biggest problem encountered is running the power cable. As many others do, I prefer running directly to the battery. The problem with the Taurus, as with many other recent vehicles, is that there are no spare holes in the firewall---at least not that I can find.

So, I went this morning and talked to a local Ford salesman that I happen to know personally (of course buying our last 4 cars from him certainly helps) and asked him how to do it. He didn't know, but took me to talk to one of their mechanics (you've seen the type---middle age, hair starting to grey, grease on shirt---the kind thats been working on cars since he was 15). Evidently this guy also does radio installations for some of their dealer vehicles.

The grass roots, doen in the trenches answer is this:

1. Locate the rubber boot around the steering column, here it goes through the firewall. Using a screw driver or similar tool lift up the edge of the rubber boot and shove your cable through. Seal around it with RTV.
2. Remove the glove box (he assured me that this is easy to do). There is an unused grommet behind it, left over from when the car radio antenna was mounted up front (at least on the Taurus).
3. Drill a hole in the firewall and mount your own grommet. Or use a bunch of RTV.

His only other comment was to stay away from the exhaust manifold, as it would melt the insulation. I might also add to stay away from moving parts, too.

Robert Cole wrote:
"Put another way, should the overall length of the antenna be 102` or 102` 3 1/3`` ?"

An example may be found in microwaves. The RSGB 3rd edition of "VHF-UHF Manual" has a dipole dishfeed for the 23 cm band on page 8.67.

23 cm is 9 inches. The dipole is 4 & 7/16 inches tip-to-tip, or just 5% short of 1/2-wavelength as expected for "end effects".

The tip-to-tip length of a dipole need not be adjusted for feedline spacing.

Well, I gave an answer, farther down the thread, that actually is more on subject, liquid antennas. I told him where to find a group that knows about them and builds lots of them, which is more than anyone else seems to have done.

Looks to me like most of the regulars on this newsgroup, except Roy and a couple others, talk about anything except the subject/question that started the thread. Which is their right. Just don't get annoyed if I point out that fact occasionally. Also the fact that anyone with an IQ above room temperature knows mercury has to be handled with some care.

The thing I don't like about this method is it puts your primary heavy
current wire (which I would hope would be fused), in direct contact with
a metalic edge. After awhile, with road vibration, the insulation will
wear through to the wire and short out.

> 2. Remove the glove box (he assured me that this is easy to do). There

This would be a good choice if the wire routing would be away from hot
manifolds, etc. I also like to use some wire loom when routing my
wiring. This give it added protection.

> 3. Drill a hole in the firewall and mount your own grommet. Or use a
> bunch of RTV.

I have done this a few times and again, as long as you stay away from
hot manifolds, moving parts, etc., its perfectly fine.

Hi Jim,

You should take care with my perverse generalizations, especially when
you follow it with:
>The main attraction of the Lattin is its claim to multiband operation.
>Otherwise one might as well go with a plain dipole.

A plain dipole is already mutibanded. This particular claim is easy
to achieve. It may not fall within interesting bands, but history
already suggests one dipole often serves more than one ham band if one
can accept the short comings (wrong directionality being key).

This is more a matter of the dichotomy of need: match and launch.
There may be more matching options than actual application of where it
is launched (too many lobes in the wrong directions).

In this sense, the trap serves to shorten the antenna to RESTRICT its
physical to electrical wavelength ratio to a quarter or less, thus
guaranteeing a mediocre performance from precious air space and
real-estate. If Art hadn't been nailed for a design 17dB below a
simple vertical, he would be here howling efficiency per unit length
(but, unfortunately in the wrong aspect - that's how you lose 17dB
behind the sofa).

Frankly, the Lattin has yet to prove to me that the notion of a
longitudinal stub as "trap" really holds any water. I've seen the
same "theory" applied to diametrically opposed designs. It is
pleasing to the arm-chair designer to mutter these ideas, but these
so-called streamers needed to make it work just yell foul on every
street corner. It is an ad-hoc design draped with academic mumblings
to lend it the appearance of legitimacy.

To extend my quote above, I have added yet another dozen measurements
to have nailed down patterns that emerged with the basis of a
consistent building paradigm (yeah, I know, gobbldygook). I seek to
generalize such claims as the Lattin makes and reduce them to a

practical minimum that are robust and repeatable. This is not to say entirely useful, nor optimal.

I did the same thing with the fractal with 300 or more measurements and reduced that junk science to a simple observation: you can push more resonances into a length of wire, the more you kink it. Useful? The test of time has shown that no one has made any money from those same published 300 pages - why would I expect the Lattin to emerge from 5 decades of neglect to eclipse that record? Frankly, the Lattin simply confirms this simple observation, but is more controlled. It may mature to a more repeatable design, but I doubt its inventor would recognize it.

Well, he also mentioned the possibility of poking a hole in the steering column boot. That may not be too bad, as there seems to be a lot of room there.

Cathy

Thanks to a couple hams in this city, Golden Valley MN has very nice antenna "restrictions". I don't know all the rules, but as I understand things, the city essentially matches most of the FCC regs. The only thing I would check on is maximum tower height. A large number of antenna installations are allowed with no permissions at all.

Feel free to email me at throwaway27 at taring.org

Golden Valley is very ham friendly. The city donates space in the Public Safety building for our W0EF club station. See http://www.tcfmc.org We have a full 2-position contest station on MF/HF, antenna towers atop the building, etc. They also provide a free meeting room for our club meetings, and break-room facilities for coffee/snacks during contest weekends and club meetings. The only "cost" to our club is that we provide a 2-person Skywarn team at their EOC during severe-wx.

1323. 1/4 wave mag mount ground?

Newsgroup: rec.radio.amateur.antenna
Date: 2004-04-23 02:33:34 UTC
From: The Masked Marvel <s_crook_remove_underbars_@comcast.net>
Message-ID: <1g%hc.5154$0u6.1124791@attbi_s03>
Source record: 96075

With a regular 1/4 wave (or 5/8) mobile whip (VHF and/or UHF) the coax normally is grounded to the sheetmetal to form the ground plane -- but a mag mount lacks the ground at the antenna end of the shield, though hopefully the metal of the body is ultimately connected to the transmitter chassis and coax braid (assumes ground braids for trunk lids etc. for rear deck lid mounts), so is there a significant performance penalty for the mag mount vs the same whip on a grounded base at the same location?

Well, it depends. The antenna does not need a DC ground path to work well. Inductive/capacitive coupling to an adjacent metal surface is generally adequate. But there are so many installation specific issues that it is not a simple answer. However, most people are unaware that one of the best antennas for 2m is a 1/4 whip in the center of the roof. At highway speeds, the 5/8 whip bends over and distorts the pattern and causes a null in the forward hemisphere. For stationary instances, the gain antennas may indeed offer gain over the 1/4 wave. Just some thoughts...

If you want to keep your ham license my advise to you is not to make any
conversions to 11 meters. CB radios still need FCC acceptance. If you
want to undertake the task of getting the acceptance then disregard my
previous advice. BTW the tests to obtain acceptance should only cost you
1 or 2 hundred thousand dollars if you are lucky.

Okay, what I ended up getting was a Larsen... A 5.8 wave... I'm using
a diamond mag mount (pinched my fingers on that sucker... Good
magnet!) Had to get a SMA adapter... I told the guy to include it,
and he didn't... Good guys at HRO though... No shipping at least.
Fast delivery. Can't ask for more than that, really...

I look forward to giving it a test flight tomorrow. Thanks for the
information folks! It really helped.

The other John Smith wrote:
"They tell me that shortening the antenna (folded monopole) below resonance will lower the resistance and introduce capacitance."

I believe that is only half right. A too-short (less than 1/4-wavelength) antenna worked against a ground plane will have a lower resistance than a 1/4-wave antenna. But, unlike the open-circuit less than 1/4-wave whip, which has a series capacitive reactance, folding the too-short element not only transforms its resistance to a higher value, it reverses the sign of the input reactance. The too-short folded monopole has a series inductive reactance.

Just like the shunt-fed grounded tower antenna, the inductance can be tuned out with only a simple series variable capacitor, not an inductor as is required with a too-short whip. See Fig 19, page 6-10 of the ARRL Antenna Book, 19th edition for an example of a shunt-fed tower capacitor tuning arrangement. The shunt-feed arrangement makes a too-small loop just as a short folded monopole does.

Q of the folded monopole is lower than a whip because the folded antenna is fatter. This gives more bandwidth.

Best regards, Richard Harrison, KB5WZI

I have done that and that is not a bad method as long as you don't get too close to the steering column or the other edge. When I used that method it is, "inspect, measure, reinspect, remeasure, re-reinspect, re-remeasure" to make certain I am not getting into anything on the other side of the bushing or getting too close to the column or the firewall.

Looking at graphs of how the waves form on the wire, that's what
I was thinking. But illustrations like the uppermost one on:
http://www.astrosurf.com/lombry/qsl-g5rv-2.htm
had me confused. I guess it's just wrong.

1334. Anecdata: was Re: Lattin antenna.....more info sources.....experiences

Newsgroup: rec.radio.amateur.antenna
Date: 2004-04-23 10:19:29 UTC
From: David J Windisch <davidw@copper.net>
Message-ID: <4088edfd_4@newsfeed.slurp.net>
Source record: 96085

Hi, all concerned:

Here's some anecdata (sic) ... :

OUAT, after reading something some where about the Lattin Labs antenna, I
put an 8-ft stub on the side of a 33-ft verticaloverlotsaradials.

I got a "new" indication of low-Z near 10M which wasn't there B4, to go
along with the 40M low-Z reading.

Received noise on 10M went up, from a well-defined nearby source, suggesting
that the el pattern might have come down some.

I moved the stub nearer the top, and found what I remember as a 3/4-wave
low-Z indication on 10M.

I think the KT-XX series of "diametrically opposed designs" use this method
of multibanding, as well.

Might even try this anecdata in Roy's Toy3, to see if its gui-ed
algorithm-ized academic mumblings prove this scandalous anecdata.

Shucks, if it can't be modeled, it can't be made to happen ;o)

Right?

Hi,

Good info, just like to add this tip:

Most cars the hood release cable runs past the battery on the way to the
hood latch up front.

You can run your cables along the same route, throught the firewall
with the hood release cable.

Robert Kole provided a link to a G5RV antenna attachment from astrosurf.com. I enjoyed reading the attachment but I believe it questionable when it says:

"---erect the antenna at an average height of about 10.35m (34 ft), which happens to be the optimum efficiency on 160, 80 and 40m bands for any horizontal type antenna"

"In practice few amateurs install masts of the optimum height on 80 or 40m, and certainly not on 160 meters."

I agree that often amateurs are limited to low mast heights, but not being able to reach the heights needed (1/2-wave which eliminates energy waste directly overhead) doesn`t make a lowered antenna optimum, just feasible.

Best regards, Richard Harrison, KB5WZI

Mike, ZL1BNB wrote:
"I`ve got a simple UHF return loss bridge and a counter.

What else do I need?"

To measure the resonant frequency of the 450 MHz dipole, you need an appropriate variable frequency signal source.

Return loss is the difference between incident and reflected powers at the antenna. At resonance, antenna reactances cancel removing a large impediment to power acceptance by your antenna.

Energy absorbed by the antenna is not reflected back toward the signal source so you have the greatest difference between incident and reflected powers near resonance (greatest return loss).

Best regards, Richard Harrison, KB5WZI

1339. Ladder line question ????

Newsgroup: rec.radio.amateur.antenna

I have the 50 foot tower, it is right outside the shack window, so will be drilling the two small holes in the sill, then fishing through approximately 12" or 18" then replace the spacers to keep the distance between the leads constant. That leaves the remaining 98 feet outside of which I need a distance of approx 35 or 40 feet of the ladder line to reach my center fed 80m or two wires 66feet each leg. What are my options with the left over 50 feet (approx) of ladder line? Coil it up? Cut it? And what are the rules about keeping the ladder line away from the tower and steal guy wires that are not insulated? I only want to do this once now and first time using the ladder line, all suggestions appreciated, thanks.....

Source record: 96091

I've recently done some NEC-2 (MultiNEC) modeling of folded dipoles which might help answer some of your questions. Translating the results to folded monoploes should be fairly straightforward.

The model is a half-wave folded dipole for 14.2 MHz in freespace, resonant at 33.15 feet using #18 wire with 2 inch spacing. The center-fed input impedance is 289 - j0.01, which is 4 times the resonant impedance of 72 ohms for a conventional dipole. A folded 1/4-wavelength monopole would have half that impedance, or about 144 ohms.

Examining the R-X curves for this dipole shows that it has characteristics very similar to a 3/2-wavelength dipole, operating at its third harmonic, and on a relatively low-slope part of the curves, indicating a low Q and good bandwidth, similar to a fat dipole.

Shortening the antenna increases capacitive reactance, as might be expected. However, input resistance *increases* as the length decreases, which is contrary to our experience with common 1/2-wavelength dipoles. This is because we're on the high side of full-wave resonance, where very high resistance values exist at its peak. As we shorten the antenna, we're climbing the full-wave resistance curve, which peaks when the antenna length is 22 feet. If we further shorten the antenna past full-wave resonance, we now begin experiencing a "normal" decrease in resistance as we "slide" back down the low side of the full-wave resistance spike. However, capacitive reactance has now quickly changed to inductive reactance as we crossed full-wave resonance.

If we continue to shorten the folded antenna length, we come to a length of about 17 feet where the input impedance is 50 + j2000 ohms. Notice that the impedance is *inductive*, not capacitive as we are accustomed to seeing with ordinary short dipoles. The inductive 2000 ohms can be cancelled with a series capacitor (or other suitable matching network). Q has increased (because we're on a relatively steep part of the R-X curves) and bandwidth has narrowed considerably from the resonance at 33.15 feet.

So, by reducing the length of the 1/2-wavelength folded dipole from 33.15 feet to 17 feet, we have a 50 ohm resistive impedance by matching the inductive reactance with a capacitor (or split capacitor) instead of the usual lossy, low-Q loading coils. Gain and patterns appear to be the same as a conventional dipole.

Translated to a monopole, the length would be a little more than half the dipole's 17 feet, to boost feed point resistance from 25 ohms to

50 ohms. My guess is (I haven't modeled it) that this antenna
functions much like a 3/8-wavelength monopole, although much shorter.
Actually building this antenna and placing it the real world will
obviously change the above values.

Unfortunately, it doesn't appear that any combination of element size
and spacing will offset the need for impedance matching with the
shortened folded dipole or monopole.

I hope this makes sense. I'm sure Roy, Cecil, Tom, and others might
have comments/corrections that will be helpful to me and others who
are relative neophytes in the wonderful world of antennas.

1344. A Lattinate Design

Newsgroup: rec.radio.amateur.antenna
Date: 2004-04-23 18:04:39 UTC
From: Richard Clark <kb7qhc@comcast.net>
Message-ID: <kgji80l1s78olc0se2uns9eruf4bmf8dak@4ax.com>
Source record: 96094

Hello Fans of the Lattin persuasion,

This is a tickler design to show how little is required to come up
with similar claims of multiband operation.

First a description of the radiator:
1. 18 meters tall;
2. two #12 wires separated by 10cM;
3. wire 1 fed against Real/MININEC ground of medium characteristics;
4. wire 2 trimmed 10cM away from ground (shorter, then, than wire 1);
5. wire 1 and 2 connected with 10cM lead, 5.4 meters above ground.

3.7MHz 30 + j3 0.28dBi @ 25ï¿½
10.5MHz 70 + j7 1.34dBi @ 15ï¿½
21.4MHz 103 - j6 5.85dBi @ 55ï¿½
28.8MHz 69 + j2 6.54dBi @ 65ï¿½

If this were developed as a horizontal, it would exhibit more Z, but
the gain figures would be more useful (and certainly higher than a
Lattin design).

I would note, with some of Roy's proviso's observed, this antenna was
derived from fundamental measurements from a suite of tests, and then
scaled to this design. Scaling worked as well as expected.

I would forecast that 20M could be brought in by changing the short to
7 meters above ground (80M would lower a bit; 15M would be iffy; and
10M lost)

>Just a thought!!

That thought has been raised by numerous people, over the past couple of decades (ever since MS-DOS viruses began to be a significant problem).

I've never heard anyone put forth *any* credible evidence at all, which indicated that the commercial anti-virus-software companies or programmers had had anything to do with writing or releasing the viruses.

Based on what I can see, the motives behind virus and trojanwriting are:

- Ego and bragging rights. Releasing a virus which spreads widely and gets a lot of visibility in the press provides the author(s) with a sense of importance.

At the moment, there seems to be an ongoing battle between the authors of two or three of the currently-most-active virus/worm families. They're actually releasing viruses or worms which [1] contain code to identify, and remove their rivals' viruses, and [2] contain bragging "We're the best, they're all losers!" statements embedded in the code.

- Spamming ability. Quite a few of the more recent viruses, worms, and trojan horses contain software which installs specialized email-processing software and web/email/TCP proxy servers. A large percentage (half or more, I've heard) of the spam flooding the Internet is now being sent through home PCs on DSL and cable-modem networks, which have been compromised by these viruses. Previous spam-fighting efforts had succeeded in shutting down many of the open email relays, and poorly-installed open proxy servers that the spammers had been abusing, and it's widely believed that major spam-gangs have commissioned virus-authors to implement these viral mail relays. The motive, in this case, is profit: spammers can flood millions of people with spam at almost no cost, and even a handful of sales can earn them enough money to be worth the effort.

Yes, I now understand. I mistakenly said shortening the length of a
non-folded monopole lowers resistance and raises capacitance. I have done
some modeling in EZNEC and with a Smith chart as Roy Lewallen suggested and
learned a great deal. I would have done this earlier, but I didn't know I
could do it the way Roy said.

Thanks to all respondents, and to you two in particular.

John

Oh yeah, like the tesla coil-flourescent light trick.

Ok, but will the neon lights be able to show you the high voltage nodes and the high current nodes on the antenna, depending on their location along the antenna? Is the brightness of the neon proportional to the RMS voltage?

Or is the brightness only proportional to the effective radiated power?

Slick

There is a significant amount of capacitance between the base of the magnet mount and the roof. Some mag mounts have special arrangements of conductive material, sometimes a foil which is on the bottom and is (usually) insulated by a thin plastic membrane. This provides a low impedance or Capacitive reactance to the roof at the base of the antenna and therefore is effectively an AC ground as far as the antenna is concerned. I have often wanted to measure it, but haven't yet. The ground through the coax, rig and negative power lead is completely irrelevant for the RF. This is because the distance along this path presents a significant impedance (without going into too much detail) and should be considered, for all intents, an open circuit at RF.
My 5/8 MFJ has surprisingly little wind induced bend at the kind of high speeds I travel (60 mph). Thicker whip sections are better in this regard.

1352. Re: Folded monopole dilemma

Newsgroup: rec.radio.amateur.antenna
Date: 2004-04-23 23:19:45 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <108j94ibv24cv45@corp.supernews.com>
Source record: 96102

Modeling a 17 foot folded dipole made from copper #18 wire spaced at 2 inches at 14.2 MHz with EZNEC shows a feedpoint impedance of 46.1 + j1893 ohms. This can be resonated, as Richard Harrison recently pointed out, with a series capacitor. There's no free lunch, though -- at 1 kW, the voltage across the capacitor is almost 9000 V RMS (about 12,000 volts peak), and even at 10 watts, it's almost 900 volts RMS. Besides concerns about arcing, you'd have to make sure the insulation across the capacitor is very good, since even a very small leakage current will cause significant loss. And you end up with a fairly narrow-banded antenna, with the 2:1 SWR bandwidth of about 130 kHz. The loss due to finite wire conductivity is 1.9 dB, which might or might not be acceptable, depending on the particular use. Increasing the wire size will reduce the loss, but also the bandwidth -- introducing loss nearly always improves bandwidth, so reducing it narrows the bandwidth. Without wire loss, and assuming the resulting 29 ohm feedpoint impedance is transformed to 50 ohms, the 2:1 SWR bandwidth becomes 80 kHz. Like a great number of variations, this antenna would surely be useful to some people in some situations, and might well be better than some other alternatives. But here's an antenna rule you can take to the bank: Small--broad band--efficient, choose any two. Any time either a modeling program or an antenna inventor or seller tell you any different, you should be very, very skeptical.

Roy Lewallen, W7EL

Nope, absolutely incorrect. I work at an ISP, and with very few
exceptions, we get the same money regardless of the traffic. It is
therefore in our best interest to minimize traffic. This is a cutthroat
business, and no one can raise prices without losing customers.

Uhm no... If a normal customer is using more bandwidth (receiving and
sending more email, committing virus controlled DDoS attacks, etc) Internet
service providers LOSE MONEY. They pay by the byte, you don't. Most
customers pay a flat fee for internet access. This is true of most Cable,
DSL, ISDN, and Dial-up setups... they are priced based on an expectation of
'normal' usage, and the ISP loses money in 'extreme' usage cases. Why I (a
'power user') get nasty emails from ISP's and have to switch often.... this
one is good about that though.

Close, but not quite.

An ISP will buy pipes, such as a DS3 that does 45Mbps, for a flat rate per month. Theoretically the upstream provider doesn't care if 1 bps or 45 Mbps are passing through that pipe; from a billing perspective, they get the same money. But they have to play the statistical game on how much upstream pipe that they need to handle all the 45Mbps pipes they sold to ISPs like you. And eventually you get to the backbone providers, who have really really big pipes, and very expensive routers.

This "power user" thing is something I've never heard anyone in the business speak of, so I have no idea why you would get bumped. If you are not breaking the TOS agreement, ISPs don't care a rat's rear end how much traffic you generate. You buy a pipe from the ISP and you have every right to fill it if you can. The only exception to that would be that you have a maximum number of hours or bytes per month. They won't kick you if you exceed it, they just charge you an additional amount that you agreed to in your contract with them. Some ISPs may do it a bit differently, but that's fairly normal in the industry.

Source record: 96107

Well, all I can do is relate my experiences, which don't totally agree with theory.

The spacing between the wires entering the home is not critical. I have two feedthroughs for my open wire line, 450 ohm, where the spacing goes out to about 8" for 3 feet. I could measure NO change in the SWR as a result of that spacing for that distance on my SWR meters (Drake W4, Autek WM-1, and Nye Viking MBVA).

Further, in a previous location, I noticed no change in SWR when the ladder line was laid on top of a flourescent light fixture for 2 feet.

In general, it is best to cut off that excess feedline, but, in some cases adding a little back in can help with problem SWRs on some bands. With a reasonable antenna tuner (Johnson Matchbox, double balanced tuner, link coupled tuner, etc.) you should still be able to tune it in most cases.

Finally, I've made 90 deg , sharp bends with the ladder line and could detect no change in SWR.

I always listen to theory, wives tales, but give some credibility to acutal measurements as well.

73s,

Evan

Yes, and the ISP has the right to simply stop offering you service as well.

BTW, the same thing happens with cell phone usage... many plans now have 'unlimited minutes,' but in actuality your usage is tracked and people who use far, FAR more minutes than the average are usually sent warnings letters or politely told that the provider no longer wishes to offer them service.

Are you offering dial-up service only, or cable modem/DSL services?

Where I live, cable modem users get well over a megabit per second of bandwidth, and someone filling that connection 24 hours a day is going to make a noticeable mark in the ISP's overall bandwidth usage.

1360. Re: Who writes this stuff ?

DSL, dialup, T1, locally connected ethernet, wireless, P2P high speed
wireless.

And if they are doing a long term average of 1Mbps, they are very likely
breaking the TOS or have a virus or are doing file trading. Most people
just can't use that much as an average, and average is the important
word. I use a ton of bandwidth compared to a lot of people, but my long
term average is well below 50Kbps.

We manage a dormitory which is mostly grad students, and the people who
use large bandwidth are mostly file traders. These people can be
assigned to 2 groups - those who actively trade, and those who installed
a file trading program, used it and think they disabled it. Guess what,
many aren't disabled when you disable them. They may still search for
peers, and may also still run as an upload/download point even though
the computer owner thinks it's disabled. I deal with this once or twice
per week on a dorm with about 300 users.

Uninfected, non-file trading users average less than 10Kbps in/out even
though their connection is "free".

And 1Mbps sustained is fairly trivial and normal. It gets missed all
the time, at least for a while. Unfortunately it gets lost in the noise
until someone looks at ALL the MRTG graphs. And again, it may be
perfectly ok, not violating the TOS. Inwhich case all the ISP can do is
call the customer and make ask them to check for a virus. And maybe not
even that, depending on the fed and state laws.

To achieve resonance, non-folded dipoles/monopoles must be cut slightly less than 1/2 or 1/4 wave due to "end effect", so I've read. EZNEC agrees.

Is this true for the folded dipole/monopole?

Thanks,
John

Source record: 96112

Bob,
Keeping the spacing of the ladder line going through a sill
is sort of a waste of time. Make the spacing whatever is
convenient, since what is between the conductors will change
the impedance from whatever it normally is, anyway. As long as
it isn't for a very long stretch of feed line, it isn't going
to make much difference.
Keeping the ladder line away from metal objects about 3 or
4 times the width of the ladder line (what's that, about 4 to
6 inches give or take a little?).
Coiling up ladder line isn't a very good idea. If you have
any extra, cut it off and save it for later. The length of the
feed line can make a difference in the tuner's ability to get a
match at some frequencies. So, try it with just enough to reach
and if that is a problem, add a little more. You will
eventually
find a 'right' length for the particular bands you want to use
(if
you use the antenna on more than one band).
Playing with antennas is almost never a "do it one time and
forget
it" kinda thing. That's half the 'fun' of playing with
antennas...
'Doc

> the same whip on a grounded base at the same location?

There was some difference in one case where I had the chance to compare. I once had a larson 5/8 mag mount on the center of the roof. You know the common model with the black box looking mag mount... It always seemed to work pretty well as a mag mount, but eventually I tore it up by knocking it off the car once too many times...So I had to ditch the mag mount, and drill a hole and do a hole mount. Did it make a difference? Yes. Quite a bit actually. It was quite noticable anyway...I found the hole mount was superior. But I still like mag mounts...It's nice being able to slap it on any car you are in. But on my truck, I have a hole mount right in the center of the roof of the cab. At the moment, I only have a homebrew 2m 1/4 wave whip on it...I don't work a heck of a lot of 2m mobile, but I do want the antenna there ready if needed.. MK

Roy Lewallen wrote:
"Modeling a 17 foot folded dipole made from copper #18 wire spaced at 2 inches at 14.2 MHz with EZNEC shows a feedpoint impedance of 46.1 + j1893. This can be resonated as Richard Harrison recently pointed out with a series capacitor. There`s no free lunch though---at 1kW, the voltage across the capacitor is almost 9000 V RMS (about 12000 volts peak) and even at 10 watts its almost 900 volts RMS.

I agree that at 1KW input to Roy`s folded dipole the power-correction capacitor has 8466 volts across it. That`s close enough to 9 KV for me.

No single antenna fits all applications and alterations may adapt an antenna for more than one application.

Antennas have a voltage to current ratio (Zo) which is a function of position along along the conductor. Zo is also a function of conductor length to diameter ratio. Fat wires have lower Zo than do thin wires. Low Zo means low voltage (relatively).

Also spacing the folded antenna conductors farther apart lowers impedance and Q. This helps bandwidth.

Raising the current by lowering Zo is no panacea as the volts across the capacitor are Amps x XC.

The capacitance of 1893 ohms at 14.2 MHz is about 0.000006 pF. If the plate size is kept significant, the spacing should be good for 12 KV with no problem.

The Andrew Corporation folded monopoles I am familiar with were usually working with 500-watt VHF FM transmitters in our land-mobile operations. Bandwidth required was 2f + 2d, if I recall, and the (f) was maximum modulation frequency, and the (d) was the peak deviation. Bandwidth was less than 20 KHz. Half-duplex was the communications mode so we needed the antenna only to work at one carrier frequency.

It was a cakewalk. Antennas only flashed over on lightning strikes and the 50-ohm Heliax saw most of the lightning as a common-mode disturbance and rejected its passage through the coax (via counter-emf from coax distributed inductance).

The VHF Andrew folded monopole element was similar to the slide pipe on a trombone only made of stainless steel. It had clamps to hold its position once set. Andrew set its length for 50-ohms at our frequency, I suppose, and adjusted the reactance for a net zero. When we set it atop our tower we always had about 500 watts forward and nearly zero reflected power. Some of these are surely operating well at this moment

after 50 years or more, though they`ve surely accumulated many small pits from countless lightning strikes.

Best regards, Richard Harrison, KB5WZI

By my reckoning, a capacitive reactance of 1893 ohms at 14.2 MHz is 5.9 pF.

i had to switch isp's twice because their definitions of 'unlimited' did not mean 24/7 on a dialup. i was not using much bandwidth, heck i could normally only get about a 33kbps connection to them, but the modem was tied up 24/7. on one of them i was a 'charter' member who had been with them since before they opened... to give me 24/7 access they wanted to go from their 'unlimited' account charge of $20/mo to around $300/mo on dialup. i ended up buying a business isdn service for 24/7 access to get more bandwidth and real unlimited access, the total for the line and isp is about $150/mo with one static ip.... some day we may get dsl out here and that wll come down to a reasonable charge.

I didn't know I could model loops in EZNEC. But now I see that it has problems only with small loops. I guess a 1/4-wave loop is not considered small. I'll go back and try it.

My fall-back plan is to make a simple 1/4-wave resonant folded monopole and feed it with a 1/4-wave length of 75 Ohm coax. There will probably be some mismatch, but I think it will be tolerable.

Thanks, guys.

John

Clarification accepted ISP's pay for the pipe not by the byte... but if you get lots of power users it's more average bandwidth, therefore more pipe needed.

Let me see, the ones who have cut me off (rather than me cut them off) These are in the order they occur to me, not chronological:
ISP1: cut off because of excessive email traffic. I can only guess that receiving so much spam (oh, 4 years ago) got me suspended. My machine was clean of any kind of spyware/viruses, and I certainly was not a spammer. And they didn't say I was. One thing I was doing at the time was transferring some rather large files around through email regularly (was telecommuting and the company I was working for didn't have an FTP server), but I still don't think it was that much (2-3 files of 6-10 mb a week). Account was 'unlimited dial up'

ISP2: Exceeded allowable bandwidth (on my "unlimited broadband" account) 4 months running. After they warned me the first month, I asked what 'allowable bandwidth' was. They could not tell me. I looked at my usage agreement, nothing about allowable bandwidth. Was a clause about 'abuse of service', but no allowable bandwidth. I cut back my usage, dinged me the next month. Called, talked to 7 people, got one guy who said 'yes, we have a cap. I can't tell you what it is, just that you will get cut off if you exceed it regularly'. Go-go stupid national cable ISP! Cut back usage, dinged me the third month. Again, I don't/didn't have spyware, viruses, (I

don't run a virus program normally I will admit, but I use the online checks with housecall or Symantec once every month, and am careful beyond belief with material from the net. Download.com stuff gets scanned by the freebie virus program I use. I just don't keep it running. Ad aware/spybot once a month as well. No hits this year so far...) and I've never run file sharing software since I had a linux box with a linux version of napster long long ago. I know that's not active anymore, as the at the time the box was running FreeBSD, and not even on the network. Admittedly I tend to be a heavy downloader... CD iso's for various free OS's, that sort of thing. I think I've run every OS to come down the pike in the last half dozen years.

ISP3: One month and out. 'Unlimited' dial-up account. Terminated for using ~320 hours in one month. Admittedly I was running a trader in EverQuest... you have to be online to enable people to purchase from you in that game. That was avg 2-3 hours a night playing, 9-10 hours from morning till I get back from work with my bot online (better sales than overnight...), doing other things on weekends.

ISP4: Purchased Unlimited ISDN account at a premium fee. Disconnected for using 1300 hours the second month. (channel hours, 2 channels count time at twice the rate). After signing up with another ISP determined that the router they made me buy from them (We won't allow you to connect with a netgear. You must use our 3-com ISDN PoS router. Oh yes, you must have a block of static ip's if you want to use multiple computers with ISDN with us, we won't allow you to use a nat boundary. Your router will be accessible from our side so we can reconfigure it. Oh yes we charge lots of cash for static IPs.) was not working properly... would not drop channels (experiment: connect, transfer enough data to bring up BOD for second channel, disconnect network from router, go to work. Router set for 2 min BOD channel drop and 5 min inactivity timeout. Router still online when back from work.)

So it's out there... you may not do it (I applaud you). the ISP I worked for didn't do it (they tracked hours and bytes, but unlimited accounts were just that, unlimited), and my current ISP isn't looking over my shoulder too much, but it is out there.

Besides, to get back on the original topic, nothing you said refutes my point (and I am not saying you wanted to, please understand that. I think you actually agree with me.), which is that ISPs (except when they charge for overage or overtime, and most accounts don't have provisions for that.. at least most I've seen do not) do not make more money on heavy usage. They make the most money on light usage. Therefore the ISP's are have little to no motivation to write these viruses.

Now if you will excuse me I have 5 machines to work on who use the local cable provider that appear to have the latest infection... presumably because the cable ISP's entire virus protection scheme involves auto detecting if someone seems to have been infected (lots of email outbound traffic) and shutting them off till they come in with a clean bill of health from a tech, and a receipt that shows they have purchased Norton antivirus (only Norton... nothing else will be accepted) and presumably installed it.

need polarization, gain and amount of backlobes, portable?
one panel type is 4 helical beams, comes out almost on 50 ohms, high gain
a flat type is stripline in/on a PCB, elements or slots are fed to center
point
Another type easy to build is using a gallon paint can with feed about 1/4
wave from the back(not panel type)

After I posted this, I learned that EZNEC would handle the loop formed by a 1/4-wave monopole. So I modeled it and found that the answer to my question is yes.

Just bought a secondhand A3S 3 element HF beam (bought it really cheap but its as well!) The fibreglass isolator is cracked so managed to get a new isolator.
What suprises me is that the isolator is made of fiberglass tube rather than being solid especially as it must take quite a bashing in gales.
Question to owners of this or other beam with a similar isolator:
Anyone replaced it with stronger material and if so can you send me info (taking out the spam trap in the email address)
Thanks in advance.

Roy Lewallen, W7EL wrote:
"By my reckoning, a capacitive reactance of 1893 ohms at 14.2 MHz is 5.9 pF."

Dang me and my sliderule. Neither of us keeps track of decimals very well. 6 pF can be obtained with wide spacing and high breakdown volts with small plates. I don`t see much of a hurdle to clear because 6 pF is a small capacitance.

As a practical matter, Andrew Corporation used another method to tune its folded monopoles, I believe, because they had d-c continuity. They supplied these antennas for decades to work at VHF. To move from 10m to 20m brings problems of scale, mechanical and electrical.

The original question said that the open-circuit ground plane has a 35-ohm feedpoint (at some elevation), and a folded ground plane has about 140 ohms as a feedpoint. Neither ground plane matches the usual coax at the antenna resonant frequency. Commercial antenna makers advertise and deliver open-circuit and folded radiator ground plane antennas which are nearly 50 + j0 ohms feedpoint impedance at a specified frequency when mounted high and in the clear.

The folded radiator offers more lightning protection than the open-circuit radiator. The folded radiator contains the ability to step-up feedpoint impedance in cases where an open-circuit radiator would have an inconveniently low feedpoint. Most TV yagis, for example, use a folded dipole as the driven eleement due to the low feedpoint impedance caused by mutual coupling with the parasitic elements.

Most energy in a lightning strike is at lower frequencies. Tune the bands during thunderstorm season and notice where the static crashes are worse, though much of this is due to propagation, some is due to the shape of the transient. Where the folded antenna loop is small in terms of wavelength, the loop is nearly a short-circuit and differential energy is small.

I saw lightning problems solved by replacing open-circuit antennas with folded-element antennas. As lightning is an interference problem taken to an extreme, folded elements are also useful in solving some other interference problems. But there are cautions. A folded dipole has a resonance where it is only 1/4-wave from tip to tip. Its circumference is 1/2-wave and resonates. This gives a folded dipole twice as many resonances as an open-circuit dipole.

I make arithmetic mistakes more frequently when I don`t know for sure that the number I calculate is reasonable or not. I do know that 20-kV

to 40-kV sparkplug voltage does not ordinarily leap many feet through the air. I also have a formula for capacitance:

CpF = 0.225 K A / S

CpF = capacitance in pF

K = dielectric constant

A = area of one of the 2-plate capacitor plates (sq. in.)

S = spacing between the plates in inches

For air, K = 1.0006

For a vacuum, K = 1

6 pF is not much so it should be easy to create.

Best regards, Richard Harrison, KB5WZI

Now I'm confused again.

I modeled a monopole at 434 MHz. Varying the vertical element showed the terminal impedance to get lower in resistance and become increasingly capacitive as the vertical element is shortened.

I thought it was supposed to be backwards from the usual unfolded monopole.?.

Resonance will be the frequency at which the feedpoint reactance is
zero. You may have difficulty with your simple equipment determining
that point, but it will be vanishingly close to the frequency at which
the SWR is minimum -- or the point of maximum return loss -- on a 50
ohm line feeding a dipole. Be sure the line is properly decoupled
from the antenna: use a balun. Generally you won't need a counter,
because the resonance will be quite broad and there's no practical
need to get the frequency closer than a percent or even a few percent.

Cheers,
Tom

Hi Slick

Your getting above my head on that one.

I know if I move the light back and forth a few inches it will dim and then go out, there are several points along a dipole where the lamp will have high brightness and this is where I put the lamps.

I know the CBers used to put a neon lamp on the tip of their mobile antenna's. I first tried it on a 10 meter mobile and it worked fine. But on a ground plane it didn't work, then I started moving the light down the shaft of the antenna and found a spot where it did work just great.

Back in the good ole days of the Heathkit Sixer lunchbox, I could put a flourescent lamp against my mobile antenna and it would light up on transmit. I never could get it to do that when I was using the Saturn V halo though.

Hi Tom

I'm not real adept at understanding much of the lingo, but you might be able to answer a question for me.

I use standard 56k dialup. I assume that when I'm online I'm tying up one of the ISP's modems. Therefore I never stay online longer than necessary to get my work done. Although I know plenty of folks that leave their computers on and connected all the time.

My late wife, after she had her major heart attack and could not leave the house worked out an agreement with her employer to do her work at home. This required staying on-line at least 8 hours a day connected to her employer.
At first the ISP said 'no problem' you have an unlimited account.
But then they later came back and told us we needed a different service, it was still dial-up, but in effect we owned our own modems located in the ISP's racks.
After a couple of more heart attacks, she had to quit work completely.
I began using the sevice she was using for my regular dialup to retrieve e-mail, read the newsgroups, surf the web, etc. About 3 hours a day.
I received a nasty note from the ISP saying I could not use that service in place of normal dialup, it was set up strictly for my wifes connection to her employer.
I switched back to my original dial-up unlimited account, but still had to pay for the contract on the other dial-up account until it expired.
Once it expired, I left that ISP and have been with my current one ever since.

But lets get into a deeper question here.
I moved to a different state but am still using the ISP I have used for years.
I assume that my home ISP has a joint account with many ISPs around the country. I'm a ham radio operator and I can travel the country and use repeaters as a guest, because I AM a member of a repeater club.
But how does this work as far as ISP's go?
Should I change to a local ISP or is it OK to continue using one of the POP presences. How does the ISP I'm calling make any money from me?

Hi Dave

Perhaps I'm all wet on this, but I thought most reputable ISP's had a program in place that blocked outgoing e-mail over a certain quantity, configurable of course to allow certain users their needed outbound e-mail activity.

I know when I was doing a newsletter that if I tried to send to everyone on the list at once, my ISP would block the transmission and an auto-responder would tell me to contact my ISP immediately.
I would do so and tell them I was sending out a newsletter.
They would either A: up my daily mailing limit or B: tell me to break it into 25 unit pieces.

It seems to me that it wouldn't be to hard to implement a program that verified the domain of inbound e-mail. Most of the spam I do get has fraudulent headers.

Although my ISP will do the filtering for me, I still elect to receive all of my inbound e-mail, including the spam, and have my own sets of filters that knock about 99% of it out, without fear of losing a valid e-mail that I should have received.

>OK. A manometer as opposed to a thermometer.

No, a barometer.

1. Thermometer -- sealed at both ends -- height depends on
temperature.

2. Manometer -- open at both ends -- one end open to atmosphere; other
end open to space whose pressure you want to measure relative to
atmosphere; displacement from balanced level in each column dependent
on pressure differential.

3. Barometer -- sealed at top; open at bottom, which is submerged in
sizable puddle of mercury; vertical height, from surface of reservoir
to top of column (assuming adequately long tube and adequately large
mercury reservoir) dependent on pressure, but length of mercury column
dependent on tilt of tube. (sec or csc function, IIRC.)

I have heard of a couple of people converting CB antennas to 2 meter. Mostly this was just using the avaialbe hardware to make a 2m antenna. Cutting off the coil and adjusting the remaining portion of the antenna to the proper length. One of my friends tried this and it worked as well as a 1/4 wl mobile can be expected. He got a lot of "picket fencing noise" while driving which was also present when using a commercially made1/4 wl antenna. Problem was solved by going to a commercially built 1/2 wl antenna.. I ve seen some base loaded antennas that could probably easily be converted to 5/8 wl 2m antennas by cutting the radiator to the appropriate length and rewinding the coil. Just find some basic antenna building projects and figure out how you can make use of the CB antenna parts in your plans to save a little fabrication time and money.

Because EZNEC uses NEC-2 for calculations, it has the same problems with small loops that NEC-2 does. It's able to model any kind of antenna that NEC-2 can, within its segment limitation.

So it sounds like once you find an area where the neon bulb is
very bright, that the brightness will be proportional to the ERP, or
the power that is delivered to the antenna.

This might be a decent, fast-and-dirty sort of power meter, where
you can tell if something is wrong if the bulb isn't as bright as it
should be (assuming it's not raining).

Hi,
Anyone have any suggestions on how to physically realize 2500 ohms capacitive loading on a wire antenna element at 147 mhz? This works out to about .4 pf. Max voltage will be around 650 Vrms. I am familar with the various ways to make a capacitor, just can't decide the best way physically to do this. Also, how about measuring a .4 pf cap. at 147 mhz with an antenna analyzer that only goes up to 650 ohms? Measure with it stuck at the end of 1/4 wavelength transmission line? Any suggestions appreciated. Oh, and why do I want to do this, EDZ beam design I am playing with.

The stray capacitances to the rest of the world will be of the same order as the required value of capacitance. The presence of stray capacitances, not being accounted for in the design, will cause whatever it is to behave in an unpredictable manner. Your electrical "circuit" or model will be different and more complicated than what you think it is.

Methinks you should re-engineer whatever it is to something which requires a capacitance of something greater than 0.4 pF and is of a more realiseable and predictable value.

Or better still, you may even re-design something to achieve the desired performance which does not require a loading capacitor at all.

I am looking for information (any) on the DJ4VM loop antenna.
Any direction would be appreciated.

I've been hearing the term ever since I got on the net and that was in
96 with my own site and in 87 through the colleges.

>are not breaking the TOS agreement, ISPs don't care a rat's rear end how
>much traffic you generate. You buy a pipe from the ISP and you have

Maybe you don't but many do.
They price their services based on an average user and they have a
multi tiered service.

Here if the average user is on 32 hours a month they don't complain
until you hit around 5 or 6 times the average user.

As I'm on DSL and networked 24 X 7 I pay a different rate than the
dial up customer.

Then even as a commercial user rates are based on the "bandwidth"
used. I have both a high bandwidth limit and a lot of storage, but if
my use, or my site generates traffic beyond a given point the rates go
up, or like many sites I've attempted to visit you find the "This site
has exceeded it's bandwidth limit for today", please try again
tomorrow.

>every right to fill it if you can. The only exception to that would be
>that you have a maximum number of hours or bytes per month. They won't
>kick you if you exceed it, they just charge you an additional amount

Only if you have that agreement. Most I've seen just block access to
the site for the day, and I've come across a lot of those "this site
has exceeded...." pages.

Sure. But you can't accurately model ones made with twinlead or window line, since NEC-2 or EZNEC can't account for the effect of the dielectric.

Hello,

So if you work at an ISP, why do people never block spammers? It's always the same companies people sign up to. You have the technology to block the users completely and/or take action after doing a trace. It can be done here in the UK.

Well, that's a tough question, because the modems are a totally
different situation than bandwidth usage. Modems are a real piece of
hardware that you are tieing up. And some ISPs like to skimp on what is
relatively cheap hardware. We don't tell our unlimited users they have
the responsibility to disconnect, but we do disconnect them where
longest idle (no traffic) users get kicked if, and only if, we are near
to filling up our modem bank. It's a bit more complex algorithm than
that, but that's close enough to what goes on at our place. Generally
our users can and do stay connected until the power fails at their house.

No, I won't tell you who I work for, and no, it's not who I use. No, I
won't go into why I use who I do.

On the shared accounts between ISPs, yes that goes on, and I believe
it's based on trading the amount of service used between them, but I'm
not quite sure. If so it implies that there is cash transferred if the
hours used are mismatched. It's a large pool among lots of ISPs, there
may be more than one of these pools, and I have no idea how they really
address the balance. I live on the tech side, not the money side.

The only part I would wonder about is did the Everquest trading break
the TOS. Other than that I don't see an issue if they were truly
offering unlimited accounts. Did you run any servers? Because many
ISPs don't allow that as you probably know.

You missed revenge and or jealousy...The DOS attacks against specific
sites because they either do or say something the writer happens to
disagree with, or doesn't like.

Most viruses and worms are relatively simple and many have depended on
the gullibility of the user to actually run them. Links to malicious
sites from newsgroup postings...(See what ever star in the shower,
Go here for an interesting site) There must be users dumb enough to
click on these links. Then there are the "updates" to show up as if
they are real when in fact they are viruses, Trojans, and worms.
Popular of late is: The e-mail server will be down for a couple of
days, please click on the link to update your file so we can forward
your e-mail during the outage. Of course there were the Microsoft
Security updates where you clicked on a link that didn't go to the MS
site.

As far as money, there are the "We are making changes and need to
update your e-bay account (quite a number of businesses have been
listed). It has you click on a link and it *appears* as if you have
been taken to the proper site where they ask for your account name and
have your log in. Of course while at it you have to update your credit

card information as well.

"Some" viruses/worms/Trojans are quite sophisticated and even "call home" to check the payload for the day, or week, or what ever. Some "morph" or evolve. Some are capable of running as soon as you open the mail and some e-mail will load information from malicious sites, which is a good reason for not using HTML e-mail. Macros can make a mess. Visual basic which is part of MS office apps can do virtually anything on your machine.

Some can search your machine looking for account and financial information, credit card numbers, SS#, ... and so on..
Some leave a keystroke logger which can be checked later for account names and pass words.

I can't imagine not having virus protection AND a fire wall. I've set here and watched a probe check all the ports on the machine and when it couldn't get in it started over. OTOH no machine is invulnerable when it's hooked to the net.

In one year I received over 250 viruses and worms. Although I haven't received many in a long time, I received 5 yesterday in half an hour. These are viruses that made it past the ISPs checking.

On the tiered service, we do unlimited only, so I can't address that issue.

On the limited bytes, sounds like you are talking about a hosted site.
Totally different deal. Unless I am misunderstanding. We generally
don't do that, except on our high volume commercial customers. And then
we do charge by the byte, sort of. If a "free" site to one of our
dialup/DSL/ISDN customers gets out of hand we will speak to them about
it, of course, but nothing cuts it off automatically.

If you could see our ACLs and how our mail servers are set up you would realize just how much we, and most ISPs, work at blocking spammers. The problem is that 1) spammers have ISPs that are dedicated to spamming and 2) windows machines are easy to hijack to spam with.

Those windows boxes are virtually impossible to block because they pop up seemingly at random, then disappear. To stop 90% of the spam in the world would actually be fairly easy in my opinion, just refuse connections from Windows NT. Unfortunately that would stop a lot of legitimate email; also it's easy to spoof that the box _isn't_ windows, so we are back to square one again.

Okay, great!

I modeled a folded monopole at 434 MHz. Varying the length down from resonance, the element showed the terminal impedance getting lower in resistance and become increasingly capacitive just like the unfolded monopole.

I thought it was supposed to be backwards from the usual unfolded monopole such that it would go up in resistance and become inductive.?.

Did you go down to 217 MHz and below? If not, check it out. Should hit
another resonance at something like 50,000 +j0, and stay inductive below
that.

I did the same thing in my new Ford Explorer ... I first carefully scoped out BOTH sides of the boot, looking for "interference" issues, then I took a long, thick needle (a test pick/probe with about 3" of needle in about 5" of nylon handle) and carefully poked it through the boot in the target area to double check.

When all looked good, I removed the needle and used a sharp xacto knife to make an X cut, through which I pushed the red/black #10 "zip-cord" power cable (I used cable I bought from PowerEx along with some Andersen "PowerPole" connectors).

Some sealant (non-corrosive - don't use the "RTV" stuff that smells like vinegar - it contains acetic acid) was then applied carefully around both sides and the cable was fitted with the split, "corrugated" plastic cable sleeving that you can buy at most auto parts stores.

Remember to fuse BOTH pos and neg leads AT THE BATTERY with suitable fuses (PowerEx has fuse holders for the new automotive type fuses). You want to be SURE that the leads between the battery connection and the fuse holders are short enough and anchored well enough that no matter what you can't get a short from the positive lead to ground - otherwise, major fireworks could occur.

Good luck.

Well, you said earlier that the folded monopole could be modeled as an unfolded monopole with a shorted transmission line in parallel. I thought I understood. When I modeled the unfolded monopole, I saw it do as usual when the element was varied in length. But when I included the shorted section of transmission line and varied it directly with the element, I thought I saw the terminal reactance go inductive as the length was decreased below 1/4-wave resonance and I thought the terminal resistance went up. So, I was expecting the same from EZNEC by modeling the folded version.

I guess I'm really lost here.

I'll once again separate the "antenna" from the "transmission line" to make it easier to see what's happening.

If you're dealing with an air-dielectric folded dipole, the transmission line stub is nearly a quarter wavelength long. So at resonance, its impedance is high and it doesn't have much effect on the feedpoint impedance. As you lower the frequency or shorten the antenna, the resistance of the antenna (as opposed to the transmission line) drops fairly slowly, and the reactance becomes negative relatively quickly. This is in parallel with the transmission line, whose reactance becomes more positive as the line gets electrically shorter. If you look at the net result of this parallel combination, you get a feedpoint impedance that has a rising resistance as frequency drops or the antenna shortens, and a reactance that gets more negative.

At some frequency below resonance, the increasing positive reactance of the transmission line equals the negative reactance of the antenna, creating a parallel resonant (sometimes called anti-resonant) circuit. Just before this happens, the resistance skyrockets and the feedpoint reactance heads positive. Exactly at parallel resonance, the reactance is zero (by definition of resonance) and the resistance is very high. And just below that frequency, the reactance heads rapidly to a high positive value, then begins decreasing as the frequency drops below that. The frequency or length where you hit anti-resonance depends on the impedance of the transmission line. I fished up a model of a 17.56 foot high folded monopole with #12 conductors spaced 6 inches apart which I had lying around. It's resonant at about 13.25 MHz., where its feedpoint impedance is 143 ohms. It hits anti-resonance at about 8.5 MHz, where its feedpoint resistance is about 15k ohms. Below that, the feedpoint reactance is positive, and decreases as the frequency is lowered.

If you want to model a folded monopole as a separate unfolded monopole and transmission line (which is a way to model one made from twinlead, since you can separately adjust the transmission line length to account for the reduced velocity factor of the transmission line mode), here's what you have to do.

First, make the unfolded monopole from two wires, connected in parallel at the bottom and top, or from a single wire of equivalent diameter. Next, choose the impedance of the transmission line to be 1/4 the impedance of the actual line. You have to use a transmission line model for this, not a transmission line made from wires. Make sure it's in parallel, not series, with the source at the base of the monopole. In EZNEC, a transmission line is connected in parallel with a source if they're on the same segment. Finally, multiply the reported feedpoint

impedance by four to find the Z of the actual folded monopole.

Les,
Hygain uses the same insulator for several of their
antennas, and it can be a problem with all of them.
Replacing it with a 'solid' insulator of some kind is
one solution. I'm still hunting for a replacement for
one for an 'R-7' (the only difference is in the length).
Thought about using 'Delrin'(sp) or some other type of
plexiglas/perspex, but haven't found a source yet.
Good luck...

For sale is one UHF base antenna, model number UH-2401 from www.buxcomm.com. I bought this antenna last fall intending to use it with a GMRS base radio, but I do not have the radio anymore, so the antenna is surplus. You can find out more about this antenna at http://www.buxcommco.com/page10/ants.htm. Frequency range is 430 - 490 mhz, tunable. A few of the screws for the u-bolts are a little rusty, but they can be easily replaced for pennies at a local hardware store.

This is PICK UP only from Beachwood, NJ. I will not ship it as I don't have the original packaging anymore and don't want to pay Mailboxes Etc to pack it up for me. Asking $40 OBO.

Hi Slick

Back when I first got into ham radio, I was just a poor widdle kid and had to home brew my first couple of rigs or get some really old Eicocraft or abandoned Heath gear for the shack.
My first receiver was a simple HR10B if I have the number right and I had home brewed a simple 40/80 meter single tube transmitter.
I saved up my money from working after school and built an HW101, which I still owned up until only a few short years ago.

The only SWR meter I had was one I picked up at a swap fest for 5 bucks. I think it was originally made for CBer's but covered all of the HF spectrum, but also could only handle up to around 10 watts.

My first antenna's were simple dipoles, and because I could only afford one length of coax I connected all of my antennas spider fashion without a balun (didn't even know what one of those were back then). But fortunately, the old rigs had a lot of tolerance for mismatched loads and high SWRs. Little by little I would get my antennas in tune.
I enjoyed CW so much that I spent almost 20 years using nothing but CW on HF, having never once plugged a microphone into my HW101 back then.

After I learned to drive, I even ran CW in my car, using a military code key that clipped to my leg with a large clamp designed for that purpose. I wish I still had the abilities I had back when I was a bubble gummer! CW was just like talking to me, I heard the words not the individual letters, never had to write anything down.

Then I got sick and was out like a light for over a week, had caught that darn Hong Kong flu virus, which was bad enough, but about a week after that I was hit with Encephalitis which caused a large memory loss and I have had periods of decreasing epileptic seizures ever since. They are now about 8 to 10 years apart and mild, but wipe out small parts of recent memory.

After surviving the Encephalitis attack, CW was as strange to me as it would be someone who never ever heard it before. It was a long hard road to learn it all over again, and it gave all of those I normally talked with on CW a chance to get their come uppance by getting even with me by using higher and higher speeds. I never regained my ability to hear the words as plainly as before.

A number of years later, long after marriage, kids and eventually buying a home, a mild seizure caused my engineerings skills to deteriorate considerable, but at the same time made learning

electronics a snap. Things at work were virtually over my head and I left that engineering companies employ and went to a company where I worked my way into chip level repairs in their electronics division. Everything just came natural to me, almost like I knew it my whole life. There was not a circuit board problem that I couldn't fix. Then after working there for about 4-1/2 years, I got hit with another seizure, this one a little rougher than the last.
The boss liked my work and held my position open for me. I went back to work, but wouldn't accept any pay until I could get back into the swing of things. I tied up a station for almost three months and could not grasp anything. Even trying to repair a simple analog power supply was far beyond my capabilities and I just wasn't getting anything back. So I left and got back into something I had done from my youth, and for the rest of my life had stayed away from anything learned beyond the age of 18, as I never forgot things from back then, except the CW from my first sickness.

I was working in electronics when I designed the antenna's I placed on my web page, they were good designs and worked great. I could run with the best of them in describing the hows and whys these antennas performed so well for me. But along with my memory loss in electronics, also came my memory loss regarding these antennas, other than I know they worked. I can look at my calculations and formulas and just go duh, having no idea what they mean. It's very frustrating to say the least. Makes one look like a blithering idiot most of the time, especially when you talk to someone you had given excellent advice to years earlier and now you can't even tie a shoelace so to speak!

My web pages went unchanged for years because I couldn't remember how to access them or write the changes in .html, had to learn that all over again too! A royal pain.

Although you don't hear about it much, there are about 1 in every 10,000 who have the same types of problems I do, and about 1 in every 1,000 who suffer from the same illness, just affected in different ways, like loss of large or small motor skills, temporary deafness, temporary blindness, that lasts for months or in some cases permanently, etc.

I have been one of the fortunate ones if you view it in a certain light. I may forget everything, but something else has always seemed to take it's place and be so sharp that it becomes natural to me. The downside is, you have to change jobs every few years. So I decided to work for myself, that way I wouldn't disappoint another employer down the road who came to count on me. I've tried, but I just can come to firing myself, hi hi.....

TTUL

Thanks Tom

My ISP boasts something like 1,500 POP presences accross the country.
So almost anywhere I travel, I can access my account just like I was
at home.

My ISP knows I have moved permanently to a different state and has had
to make changes to allow my access to things like newsfeeds etc.
Because he is relatively a small provider as compared to most others,
I have never found one better or as concerned about his users.

My take on the situation is, he probably has many more outside clients
of this ring he belongs to using his services as they travel, than
what our few members use outside of his service.
So, if there is a fee, he is probably on the receiving end if money is
involved.

Being totally illiterate about how the internet actually works, but
being conscious of the local end of the wire. I set my computers to
disconnect if idle for 5 minutes. But at the same time, I do spend at
least 4 hours per day on line.

As long as it's Kosher, I would like to remain with my current ISP!
But at the same time, I don't want to make whatever ISPs phone numbers
I am using to get disgruntled about it. I may be breaking a clause in
a contract between ISPs and not even knowing about it.
I have absolutely NO idea what ISPs I work through, as my own ISP
provides only the dialup telephone numbers we use nationwide.
Although, because I'm here permanently, he did give me a different
phone number to use that does not appear on the travelers list of
numbers.

Thanks for your input Tom!

Thanks for that.
I took it that Cushcraft would have tested the antennas to destruction, so thought I was being over causious but have heard from others that the fiberglass breaks down after a while as it ages.
I have managed to get hold of an original (or at least its on its way) If I an get a replacement I will the first chance I get.
Will look at Delrin on the net and see what it is. Guess the insulator is not soild due to the extra it would cost in manufacture.
Thanks again
Les

I have posted this on eHam.com, but thought I'd try here as well.

Sorry if this story is rather convoluted, but I'm in a bit of a quandary and any help would be appreciated.

I am getting back into ham radio after a ten year absence, and HF operating has always been my favorite. In the past I lived in a rural area, and could put up whatever sort of antennas I wanted, and was even pretty good at making my own dipoles for various bands.

However, I now live in a subdivision that, while antennas are not forbidden outright, the civic association is vicious and not to be trifled with, hence I wanted to go with something at once stealthy but versatile.

At first I thought to try the old stand-by, the G5RV, but in doing my Internet research on the issue, I came across this "Carolina Windom" multiband antenna, which seemed to give more bangs for the buck. I ended up purchasing one from an outfit that will remain nameless here, to the tune of around $150, when you include shipping, rope and other incidentals.

It was a bear of a job to put up, since I had to threat it through tree branches and whatnot (which is why I got the one with the insulated wire), but I got it up. Suspended from trees, the "matching transformer" (looks like a balun to me) and the long segment of wire was up about 35', more or less horizontal. The shorter end sloped down, with the end about 10' up (I had no alternative in this).

After making up the 100 or so foot feed line (RG-8X) and grounding the rig (8' copper ground rod), I hooked up my Yaesu FT-890...and the SWR was through the roof on all bands.

Anything more than a few watts, on 80 through 10m, made the radio shut down. I checked continuity all the way back to the antenna, and everything seems OK, except the balun shows a dead short on my VOM. However, the antenna maker says their balun is supposed to show a dead short, and when I took the antenna back down I could find nothing else wrong with it (no damaged insulation, all connections weatherproofed to the max, not that it had been up long enough to get wet, etc).

Except for power and phone lines running along the back property line (and the slinky antenna I put up later is no further away from those than the Windom was, and I am having no problems with it), there was nothing metallic nearby to detune the antenna, and even if there was, I can't imagine even that would create the high SWR I am seeing.

I called the manufacturer up and after telling me there was nothing wrong with the antenna based on what I told them, they just said to send the

antenna back to them and they would "check it out".

We finally get to my question. I have been working on getting an antenna for weeks, and am tired of fooling with assorted vendors (have dealt with several during this process, and none have impressed me).

Given how much I will pay out further on shipping the antenna both ways and the like, I am wondering if I would be better off simply buying a decent 4:1 balun, replace the existing "matching transformer" with it, and use the rest of the antenna components (wire, coax, RF choke), and if so, is this more likely to work? Based on my research, the original Windom antenna design used a 4:1 balun, and the wire lengths of the antenna I bought look to be pretty close to specs per that design, which is why I suggest this option.

Unfortunately I am no antenna guru, and even with all the information I've found on the Windom, the data is a bit ambiguous on this point. So, before I throw any more good money after bad, I would appreciate any help you all could give me in this matter. Thanks and 73.

PS What to take out of my email address to make it work is pretty obvious...:)

John wrote:
"I`ll go back and try again."

John has the best help there is in Roy Lewallen, the creator of EZNEC. The idea of breaking the behavior of a folded dipole or unipole into its differential (transmission line)-mode and common (antenna)-mode behaviors goes back according to Paul H. Lee in "The Amateur Radio Vertical Antenna Handbook" to W.V. Roberts, "Input Impedance of a Folded Dipole", RCA Review, Vol.8, No.2, June 1947, p. 289.

Around the 1/4-wave length, the folded monopole`s resistance is steadily rising with frequency. High radiation resistance as compared with loss is good. This happens with the open-circuit 1/4-wave vertical too.

Around the 1/4-wave length, the folded monopole undergoes an abrupt change from inductive reactance when it is too short for resonance to capacitive reactance when it is too long for resonance. The open-circuit whip undergoes a similar change but it has a capacitive reactance when it is too short for resonance and an inductive reactance when it is too long for resonance..

One contributor to this folded monopole thread said he found a coil shunted across the feedpoint of an Andrew Corporation folded monopole. On page 26-12 of my 19th edition of the "ARRL Antenna Book" is described a matching technique using such a coil. It`s called the "helical hairpin" (with tongue in cheek). This method seems convenient, in conjunction with length adjustment of the folded monopole, to get a 50 + j0 impedance at the specified operating frequency. I am not privy to Andrew`s actual practice as we just placed the orders and the antennas worked as advertised.

Figure 17 on page 6-9 of my 19th edition of the "ARRL Antenna Book" is very similar in appearance to the Andrew Corporation folded monopole. There is a lot of good information in the Antenna Book on folded antennas, and more.

Best regards, Richard Harrison, KB5WZI

Pat, before you jump off the world do you live near other hams or have a
ham club nearby? The reason I ask is that an Antenna Analyzer would help
understand what's happening. Not every ham owns one, but, generally
there are several hams in a club of 50 or more hams who would own one.

1422. PCB Loop antenna using Ensemble Sv

Newsgroup: rec.radio.amateur.antenna

From: Lance <lscarey@pclv.com>
Message-ID: <CXUic.37514$dZ1.143@fed1read04>
Source record: 95972

I looking to layout a loop or spiral antenna using ensemble sv.
Has anybody done this? I have completed some designs with the software based on some application notes. My problem is I having difficulty matching 50 ohm impedance and a VSWR of less than 1.5.
If someone has done this I would appreciate some advice.
Thanks

There are simpler, cheaper ways to accomplish the same end, so let's
just make the best of what you got.

>After making up the 100 or so foot feed line (RG-8X) and grounding the rig
>(8' copper ground rod), I hooked up my Yaesu FT-890...and the SWR was
>through the roof on all bands.

A copper ground rod is only good for an AC safety ground. If you want
an RF ground, you need some radials. We will skip this for the time
being.

>Anything more than a few watts, on 80 through 10m, made the radio shut down.

This is a symptom of Common Mode problems. Your feedline is
radiating. How much is immaterial until it causes the shut down. It
is apparent that the BalUn is a conventional 4:1 with no choking
action (no point in asking them why not). Put a 1:1 Current BalUn
just before it, or wrap your coax into 6-8 loops of 6 inches (at the
feed point).

>Except for power and phone lines running along the back property line (and

None of these will be so disruptive. It is Common Mode problems.
>

A waste of everyone's time.

The choke (or added 1:1 Current BalUn) should fix it to the point you can tune it in. You ARE using a tuner are you not? This isn't a magic antenna.

The only multiband wire antennas (with names) that do not require tuners are the ones that come with resistors built in. You did not purchase this option. You WILL need a tuner.

This is what I'm trying to see using EZNEC. I agree with the resistance
trend, but I keep seeing capacitive reactance below 1/4-wave resonance and
inductive reactance above 1/4-wave resonance.

I see no difference in the trends.

Hey, Richard -

Take a look at Roy's second paragraph:

"If you're dealing with an air-dielectric folded dipole, the transmission
line stub is nearly a quarter wavelength long. So at resonance, its
impedance is high and it doesn't have much effect on the feedpoint
impedance. As you lower the frequency or shorten the antenna, the
resistance of the antenna (as opposed to the transmission line) drops
fairly slowly, and the reactance becomes negative relatively quickly.
This is in parallel with the transmission line, whose reactance becomes
more positive as the line gets electrically shorter. If you look at the
net result of this parallel combination, you get a feedpoint impedance
that has a rising resistance as frequency drops or the antenna shortens,
and a reactance that gets more negative."

What Roy is saying is also what I'm seeing with EZNEC. You are saying the
opposite reactance occurs with a folded monopole.

Seems like everyone I talk to about using ladder line to my proposed 540' horizontal skywire loop does a double take when I say I want to use ladder line into the shack. I was curious if there are any fans of ladderline feed systems who can relate positive experiences, or am I about to really court disaster here.

The ARRL antenna book says that coax to this type of antenna is not as "multiband" friendly as was once fantasized....they recommend ladder line.

Anyone actually have such a loop? What is your experience?

The advise you have been given is good.
I will tell you my experience of Windoms. I built my own via info in the Radio communications handbook, loads of info is on the net anyway. I have a 4-1 balun at the point where the 2 horizontal wires meet and a 1-1 balun at 22ft down from this. My antenna elements run as horizontal as possible and the downlead drops down and as far away from any object that I could make it. It works brilliant THROUGH A TUNER. In my opinion you will never get the swr quoted by all the manuafactured windoms without a tuner.
BUT dont worry about the swr being a little high. All multiband antennas are a compromise, but how many of us can put up a dipole for each band.
Good luck youll find the windom works well. Basically Im saying use a tuner and dont get stressed out about the swr.

Les

1430. Re: Transmission line radiation

Newsgroup: rec.radio.amateur.antenna
Date: 2004-04-25 22:07:36 UTC
From: richardharrison@webtv.net
Message-ID: <9270-408C36A8-237@storefull-3251.bay.webtv.net>
Source record: 95980

Ron Wrote:
"What happens to cause radiation to begin?"

Ronold W.P. King wrote in "Transmission Lines, Antennas, and Wave Guides, by King, Mimno, and Wing on page 224:
"Any closed loop of wire that is not confined to the near zone (shielded) and that does not carry equal and opposite currents very close together (adjacent and perfectly balanced though opposite) radiates at least a fraction of the power supplied at its terminals."

Radiation is a phenomenon. Energy tries to spread out from where it is to elsewhere. Unless it encounters barriers it just continues to spread.

Electromagnetic wave radiation is sustained by perpetual regeneration from mutual stimulation. The electric wave contains all the energy for an instant. The growth and decline of the electric field creates a magnetic field which in turn creates an electric field and so on. These fields can exchange their energies in a vacuum devoid of electrons or electricity. They continue through the vacuum at the speed of light. The waves go so far so fast that much energy escapes the attraction of its source to recall it.

Terman says in his 1937 edition on page 700:
"A concentric transmission line radiates no energy under ordinary conditions because the outer conductor acts as a substantially perfect shield.

The power radiated from a non-resonant two-wire line:

Power radiated=160Isqd(pi a/lambda)sqd watts

I= line current

a/lambda= spacing in wavelengths""

In a resonant line, radiation is increased by about the ratio of peak current to load current.

Best regards, Richard Harrison, KB5WZI

I srongly suggest the Hustler 4-BTV antenna or the 5-BTV. Depending on the bands you want to use the 4-BTV does 10, 15, 20 and 40 very well. I have one and have reached Spain, Russia, South America, the Galopigos Is., and many other places far away from my Iowa shack.

It works very well.

The 5-BTV gives you 80 meter on top of the 4 offered by the 4-BTV.

73s.

Hell you can hear the same shit on NBC, CBS, ABC, CNN, MSNBC, PBS, CNBC
and any of the other liberal owned radio and TV stations.

I find it fucking funny that the liberals don't feel represended on the
airwaves and think that opening up a radio station specifically for
liberals will stand a chance against the very few Conservative stations.

The problem is, you can go anywhere for liberal views, but only a few
places for conservative ones. That is why the conservative stations have
become so successful.

Air America is already showing signs of a early death. Hell they can't
even pay their bills (probably don't think they have to since liberals
usually live off of the money earned by others).

Oh well, PT. Barnum said it best when he said "There's a sucker born
every minute" and I bet that he was talking about liberals.

LOL.

On Fri. Apr. 23. 2004, 4:19 pm (CDT-2) Roy Lewallen wrote:
"This can be resonated as Richard Harrison recently pointed out, with a series capacitor."

Why? look above in Roy`s posting:
"---EZNEC shows a feedpoint impedance of 46.1 + j1893 ohms."

The + j1893 is inductive, not capacitive. It`s the reactance shown by a too short (less than 1/4-wave) folded monopole or short-circuit stub.

I believe I am on the same page with Roy.

Best regards, Richard Harrison, KB5WZI

Okay! I did it!

I didn't separate out the transmission line from the antenna. Instead, I just modeled the folded monopole. I plotted on a Smith chart the resultant terminal impedance as the vertical element varied from .23 wavelengths to .245 wavelengths. It went from (73.31 - J 40.81) through (85.71 + J 0.7908) to (93.59 + J 22.56). Easy!

I found that a vertical element of .2325 wavelengths gave me 76.05 - J 30.27 ohms. That's a sweet spot for this particular antenna in that feeding it with a .143 wavelength piece of 75 Ohm coax will match to a 50 Ohm source.

To further my education, I also checked the anti-resonance point you mentioned.

Thanks!

John

John,
For a 1/4 wave folded monopole working above a ground plane, you have to go
below the frequency where the monopole is 1/8 wavelength before it goes
inductive. For a folded DIPOLE it is 1/4 wavelength. You are already doing
EZNEC, spend another 3 minutes with it.

I don't have a loop like yours, but I do feed a couple of antennas with commercial 450-ohm ladder line. No problems bringing it into the house. In fact, it cleaned up a few TVI problems I had when feeding an antenna with coax.

I use 450 ohm ladder line on two seperate antennas here. One is a full sized 40 meter loop, in right triangle configuration, vertical. I run the line straight into the shack and into a EF Johnson Matchbox. Works all bands 40 thr 10 just fine. I run 600 watts into it, and no problems. No TVI, No computer faults, no telephone problems.

On the other antenna I have a 140 CF doublet with 450 Ladder Line feed. This into a Heathkit SA-2040 tuner. Same same as above.

The reason I am able to run the LL into the shack is that I have a large out building that I have the shack in. Run it right through, not a problem.

Just keep the line away from conductive objects and I run it up to my ceiling then out.

>unpredictable manner.

You may be right Reg, however the capacitive loading I need is not distributed throughout the length on the antenna. Seems the stray capacitance would be distributed. In particular I need -j2500 ohms at a specific point on the antenna.
What I am attempting is to change the current distribution on an Extended Double Zepp (1.25 lambda dipole) such that the gain and F/B ratio are more to my liking. There is a published article on doing just this on a 40M EDZ. -2500 ohms at 7.2 mhz is 9pf. I just scaled it up to 147mhz to .4pf. I have tried different values of loading, and different positions on the antenna, but this seems optimum.
What I have now is a 3 element beam with 17dbi forward gain with 12 db F/B ratio, at least on paper.
>Methinks you should re-engineer whatever it is to something which requires a capacitance of something greater than 0.4 pF and is of a more realiseable
>and predictable value.
Maybe back to the drawing board? Decrease loading and change position. What size cap. would be resonable?

<snip>

Is it possible for someone to post the "file"/spreadsheet for this? As someone who uses EZNEC less than some other programs, I'm not sure how to set up the feed and the antenna in parallel.

Also, we had a nice presentation on the use of EZNEC at the 2004 Aurora yesterday by W0ZQ. Aurora is the yearly conference of the Northern Lights Radio Society. Other speakers included VE4MA, noted cutting edge moonbouncer - first on 24Ghz, covering broadband over powerline.

With general purpose, multi-band antennas such as yours, taking one band with another, the higher the feedline impedance the less the loss in the feedline.

This is because feedline attenuation in dB is directly proportional to R/Zo where R is the resistance of the feedline conductors and Zo is the line impedance. This simple relationship applies from 50-ohm coax (or lower) up to 600-ohm (or more) wide-spaced open-wire line.

Ordinary 50-ohm coax is fine ONLY when the input impedance of the antenna is itself approximately 50 ohms purely resistive and the line length is not very long. But with multi-band antennas Zin is most unlikely to be anywhere near 50-ohms on any band. It is more likely, taking one band with another, to be several hundred ohms or even 1000 ohms with a high reactance component.

Assuming the conductor resistance to be of the same order for both coax and balanced-pair lines of the same length, line loss will be appreciably less for the higher impedance lines. In fact, for the physical sizes usually involved, spaced balanced wires have a lower conductor resistance than ordinary coax and this swings the use of spaced lines further in their favour.

Even a 300-ohm twin line with substantial conductors, not the flimsy old TV downlead type, will effect an improvement over the usual sort of coax. 450-ohm ladder line is most popular because of cheapness and relative ease of installation. But for perfectionists, on very long lines, a 5" or 6" spaced 600-ohm work-of-art cannot be bettered.

With low-loss, high-Zo lines SWR on the line can usually be forgotten about. But a high SWR can make severe demands on the tuner however.

Transmission line Zo, of course, is unrelated to antenna efficiency which with a high antenna is nearly always good enough to be considered 100%.

I have owned an successfully used two of the 160 meter "Carolina
Windoms" from Radiworks. First commercial wire antennas I've ever
used, but I made the decsision to buy & not build, in order to save
time and get something up in the air quickly.

These antennas work well. Your installed height is not really great,
but if that's all you have to work with, then so be it.

Radioworks' Carolina Windom (at least the 160M version) has around a
2:1 to 3:1 SWR on the 160-10M ham bands....which pretty much dictates
the use of a tuner; with your height, SWR will probably be a bit
higher. The design has some kind of balun at the junction of the
horizontal elements, and an RF choke at the end of the 22' "radiating
feedline".

With insulated wire, I don't know what variables you'll have...sounds
like it is made by another company, so your mileage may vary.

Good luck & 73

I don't have a loop but I have used 600 ohm open wire line for years and
love it!

It does require good tuner or, in Cecil's designs, controlled lengths of
line, for a good match. I transition from ladder line to coax using a
current balun and bring the coax into the shack. This is about a 10 foot
run of coax. I run a KW when required and no problems in wind, rain,
snow or ice.

That is the cleverest thing I've seen today. Wow. Very nifty.

My only concern when constructing something like that is how to store
the longer lengths (eight and sixteen) of ladder line -- can they be
coiled up? If so, it's less unwieldy and can scale even higher.

Of course, those hams who know binary arithmetic will luck out here.

Jack.

No. The example with the positive reactance is at a frequency below parallel resonance, where the reactance goes the other way than it does just below normal resonance.

As I pointed out in my most recent posting, the antenna reactance becomes more negative at frequencies just below resonance, and the transmission line reactance more positive. Beginning at resonance, the net feedpoint reactance (the reactive part of the parallel combination of the antenna and transmission line impedances) becomes more negative as frequency decreases or the antenna gets shorter -- until parallel resonance is reached. At parallel resonance, the reactance abruptly jumps from a large negative value to a large positive value, then decreases as frequency further decreases or the antenna shortens. The example I gave in that posting showed the parallel resonance at a frequency somewhat higher than where the antenna is an eighth wave high. But the earlier example antenna with 46.1 + j1893 ohm feedpoint Z is about an eighth wave high, shorter than self resonance. Don't forget that the actual frequency of parallel resonance depends on the impedance of the transmission line, so don't make generalizations about where parallel resonance will occur for all antennas. But if you know that the folded monopole or dipole is shorter than a resonant length and its feedpoint reactance is positive, it's below parallel resonance and the reactance will decrease as frequency drops or the antenna gets shorter. If its feedpoint reactance is negative, it's above parallel resonance and the reactance will become more negative as the frequency drops or the antenna becomes shorter.

An unfolded monopole's impedance is monotonic below resonance. That is, the resistance drops and the reactance becomes more negative as you go lower in frequency, as far as you want to go. Not so with a folded monopole -- it has one behavior down to the parallel resonant point, then the magnitude of the reactance goes the other way below that. The reason is that there are two separate mechanisms at work, rather than the single one for an unfolded monopole. So if you want to make a rule about which way the reactance goes, you've got to specify whether you're above or below parallel resonance.

Those impedances seem pretty low for a folded monopole, unless the conductor diameter is large.

When modeling two parallel wires like a folded monopole or dipole with any NEC-2 based program, it's essential that the segment junctions be aligned. For the folded dipole or monopole, simply make the wires the same lengths and give them the same number of segments.

slightly off topic....

Hi Dan,

What kind of lightning protection do you employ for straight ladderline? What are the options (besides tossing it out the window) - if you aren't using any? I don't run any feeds through my windows, so I wondered what options that left for ladderline, etc.

Thanks

Jack

> long for resonance..

Not to be picky and unncessarily perpetuate this discussion, but it's already been correctly stated in this thread that a folded monopole or dipole exhibits the same impedance characteristics around resonance as a conventional antenna. That is, when it's too short for resonance, reactance is capacitive, and is inductive if too long. And resistance is 4 times the resistance of a conventional antenna, and actually *increases* on either side of resonance, according to models.

The above statements are only true in the region of operation around 1/4 wavelength (folded monopole). As frequency or length is decreased more significantly, past the anti-resonant point (something that doesn't happen with conventional 1/4-wavelength monopoles), its characteristics take on a completely different twist, where reactance suddenly becomes (and stays) inductive and decreasing, and resistance decreases rapidly.

A folded monopole (or folded dipole) is, in some respects, like two different antennas, with two different sets of characteristics, depending on whether you are operating above or below anti-resonance. One of the problems in discussing folded monopoles/dipoles is because of just this reason -- you simply can't make general statements about how it works unless you also provide some of the parametric assumptions.

You just like saying the word liberal. You don't really know what it
means but
you hear fruitcakes like Mr. Oxycotin, O'Really and that freak Hannity
use it.
You hear them throw the liberal word around in their name calling and you
think its cool to come here and do the same.
Bush is the dumbest president we have had in a long long time. He hasn't a
clue on what is going on. Chenney has his hand up dumb Bush's ass like a
sock puppet
getting George to say and do anything. Bush is a murderer. He started an
unnecessary war that
has resulted in the deaths of 711 Americans and nearly 4000 seriously
injured. And counting.
Bush has no heart or soul. I can hardly wait until the debates as Kerry
rips him to shreads and
makes Bush look like a fool in front of the whole world. He has so much
material to work with.
He is going back to Teeeeexas. God that accent makes him sound so stupid.

I've found the easiest thing is to insert banana jacks/plugs in the
ladderline just outside the window. When the clouds come, I simply
unplug.

The Wireman sells a balanced-line lightning arrester built around a
couple of spark plugs, but I'm not sure how well it works.

Edward,
I have 'good' days and 'bad' days. Seems like when
I posted that one, it must'a been a really 'bad' day.
Oh well. The 'R-7' is by Cushcraft (duh), but the rest
of it was correct. 'Delrin'(sp?) comes in all shapes
and sizes, just a form of plastic that handles RF and
sun light well. Also a brand name, and I have no idea
what the chemical composition is (other than a 47 letter
name that I could care less about). If it's an insulator,
the correct size, pretty strong, and a pretty shade of
red, almost anything would work in place of the original
fibreglass (I like red)...
'Doc

any reason that silicon sealant would not be as good as anything else when fixing (gluing) the wires to the slotted holes of the spacers in a homebrew ladder line? Any reason why this same substance would not be appropriate to seal up the ceramic tubes where such lines go through a wall?

this stuff is tough, weather resistant, sticks, and stays flexible.

Roy, W7EL wrote:
"No, the example with the positive reactance is at a frequency below parallel resonance, where the reactance goes the other way than it does just below normal resonance."

Just as the usual folded dipole selected for a particular frequency is 1/2-wave, the usual folded monopole is a 1/4-wave. Shorter or longer antennas are used and harmonically related frequencies may or may not have convenient drivepoint impedances depending on which harmonic.

The folded monopole is usually tuned to be a short-circuit stub at some particular frequency and it has the shield side of the coax also connected to an elevated radial system to keep signal off the outside of the coax, and it replaces the "missing half" of a dipole. The ground plane leaves the radiation up to the vertical antenna element.

The folded monopole antenna is a resonant system with distributed constants.

Terman says on page 893 of his 1955 edition:
"As a result, the impedance of an antenna behaves in much the same manner as does the impedance of a transmission line (see Sec. 4-7)"

Sec. 4-7 is found on page 98. Here Terman says:
"The expression "Transmission-line impedance" applied to a point on a transmission line signifies the vector ratio of line voltage to line current at that particular point. This is the impedance that would be obtained if the transmission line were cut at the point in question, and the impedance looking toward the load were measured on a bridge."

In the case of a short-circuit 1/4-wave stub, Terman has Fig. 4-10(b) on page 99 of the 1955 edition. At the load, the short at the antenna tip, the power factor is shown lagging by 90-degrees which by my electronics dictionary is:
"Laggibng load - A predominantly inductive load - i.e., one in which the current lags the voltage."

What`s more, the 90-degree lag persists almost unchanged until a point is reached nearly 1/4-wavelength back from the short.In the folded monole, that would approach the drivepoint.

If the folded monopole were lengthened beyond 1/4-wave, an abrupt flip to a leading power factor angle of nearly 90-degrees would be experienced on passage through the 1/4-wave resonance point. The phase variations become less abrupt at subsequent flip points as any added 90-degree points become farther removed from the antenna tip short-circuit. The frequency is getting higher so that the antenna

appears longer in terms of wavelength or the antenna is gaining in number of 1/4-wavelengths some other way to produce multiple phase reversals.

Best regards, Richard Harrison, KB5WZI

You must use an ATU with this antenna.
It is NOT a resonant ant on any band (the same as the G5RV, with the
exception of 20m in a good installation).
Most built-in ATU's will not handle the high VSWR on this type of ant also.
The only exception I have seen to this is the 'ICOM-756PRO', it seems to
manage quite well into the 'Carolina Windom'

Try an ATU before you start ripping down the ant and rebuilding it just to
find you have the same problem Pat.....cheers and good luck, Ken,
G4KIR.

You need to use a true 'balanced ATU' for best performance with this type of
antenna.
BalUns in a 'TransMatch' type of ATU do not make up for using a truly
balanced ATU.
Hope this helps, cheers and good luck, Ken, G4KIR.

Al, WA4GKO wrote:
"---when it`s too short for resonance, reactance is capacitive, and is inductive if too long."

Thats exactly correct for an open circuit dipole or monopole, but folded elements are backwards because they operate like loops and shorted transmission lines.

Kraus says:
"Consider a two-wire folded dipole shown in Fig. 14-27a. The terminal resistance is approximately 300 ohms. By modifying the dipole to the general form shown in Fig. 14-27b, a wide range of terminal resistances can be obtained, depending on the value of D. This arrangement is called a T-match antenna."

The ARRL Antenna Book says:
See Fig 9. Each such T conductor and associated antenna conductor can be looked upon as a section of transmission line shorted at the end. (This is also true of the short folded monopole.) Because it is shorter than 1/4-wave it has inductive (Not Capacitive) reactance. As a consequence, if the antenna itself is exactly resonant at the operating frequency, the input impedance must be tuned out if a good match to the transmission line is to be obtained. This can be done either by shortening the antenna to obtain a value of capacitive reactance (The T-match antenna itself is open-ended) at the input terminals, or by inserting a capacitance of the proper value in series at the input terminals as shown in Fig. 10A."

The too-short T-match has excess inductance to be cancelled just as does a too-small loop or folded antenna. This is accomplished by adding capacitive reactance. This is the opposite of your short mobile whip which needs a coil.

Best regards, Richard Harrison, KB5WZI

Just look at Terman`s phase diagram for a shorted transmission line and
I think you will agree with Capt. Lee.

Capt. Raul H. Lee, USNR, K6TS on page 31 of "The Amateur Radio Vertical
Antenna Handbook" wrote:
"The folded unipole feed principle may be easily applied to the short,
top loaded vertical radiator. The transformer action of the folded
unipole is used to give a more favorable input resistance than can be
obtained with a series feed. Another thing that the folded unipole feed
does is to reverse the sign of the input reactance. The input reactance
of a series fed tower shorter than 1/4 wavelength is always capacitive.
This means a series loading coil (spoken of in high power as a helix)
must be used to resonate the tower. With folded unipole input the feed
point reactance is always positive. (Consider the tower and feed wire to
be a shorted transmission line less than 1/4 wave long. Its input
reactance is positive.) Thus, the folded unipole may be fed with a
low-loss capacitive feed network.

Best regards, Richard Harrison, KB5WZI

The electrical properties of sealing materials and greases are not defined or specified. They probably make poor dielectrics when surrounding or are in between transmission line conductors. I wouldn't use the stuff. A few spots of super-glue would be ok.

There's no need to run open-wire line through walls and windows via two spaced holes. The building material between the wires will probably be of awful dielectric quality anyway.

Just bring the pair of insulated wires close together for a short distance and run them through a single somewhat larger hole lined with a short, pvc or polythene tube. Slope the tube and the line to prevent rainwater from running indoors.

When coming through glass or DRY varnished timber a single hole is fine. On high power lines make sure the insulation on the wires where they are close together is thick enough to withstand the high voltage at high SWR.

At HF, the discontinuity in Zo due to bringing the wires close together for a few inches, even a foot or more, is absolutely negligeable. And there's nothing wrong with changing from a long open-wire line (outdoors) to a short ladder line to the transmitter (indoors).

Use a simple choke balun between the transmitter end of balanced lines and the tuner. The luxury of a balanced tuner is unnecessary.

Hi, all concerned:

Re: subject: The simple answer is, "Yes". Then, it gets, well, complicated. TDIITDetails, YK.

After several fires-on-the-feedline with QRO and commercial steel-cored owl's, I rolled my own, and I close the (vinyl "AIRTITE"-brand) windows on parallel strips of copper flashing, fastened to the sills inside and out, to get up to the legal limit of r-f into or out of the shack. Parallel-tuned or series-tuned ckts in the shack take care of the coax-to-owl transitions.

It once was a quickie way to get on 160M, to yak with one's buddies, by deliberately tying together the ends of the owl feeder to an 80M dipole right in the shack, and feeding the thing as a wire against what ever ground was available. That mode can occur as an unintended consequence of simply using what ever lengths of "antenna" and "feedline" that fit one's situation. BT, DT .

I forestall many rfi problems in the shack by having several layers of aluminum foil, under the rug, with drain wires connected to equipment and earth ground. This cools metal microphones and knobs down nicely if one uses the quickie fix to get on 160M.

HTH.

You are correct again. I had different numbers of segments of the parallel wires. When the segments are about the same number, the terminal impedance goes up. I am also trying to run as many segments as practical so the accuracy is greatest.

Hi Slick

> Well, that must have been interesting to have that sort of
>ability.

Actually, what makes CW hard is trying to learn it at different
speeds. CW is entirely different at different speed levels.
I guess I should say the SOUND of a word is what is different.

When your talking to someone in person, you don't say aich eye bee oh
bee, you simply say Hi Bob

Low speed CW is like saying aich eye bee oh bee.
High speed CW is like saying Hi Bob.

A good example of this is listening for someone calling CQ, after you
do it long enough, you no longer hear the letters CQ, you hear the
SOUND the code makes for those letters and easily recognize a call for
CQ, just by the sound of it.

A new typist can tell you where every key on the keyboard is!
A seasoned typist will have trouble doing this, because the word they
are typing goes from their eyes or ears or mind, right through the
fingertips to the printed text, it's automatic, they don't stop and
think about each letter they are pressing, their fingers just do it
automatically.

Pick up some code tapes that run at 20 words per minute and you no
longer hear the individual letters, you hear words.
Good high speed code tapes work by using only a single word for
several itterations, than add a new word for several itterations, then
combine a few words into a sentence.
Pretty soon you HEAR only the words and not the individual letters.

The only time you slow your sending speed is when sending your
callsign or an unknown unfamiliar word, like an obscure town name.

In essence, you hear the PHONICS of the sound of the code that make
words, thus large words are as simple to understand as short words.

> So, did you get your case from a virus?

Yes, it was the result of high fever associated with the Hong Kong Flu
(a virus).

> Well, from the Tao, we get, "Loss can be a Gain", and in your case
>it might be that you gained by losing the boss!

I honestly have!
And really do consider myself fortunate in many ways.

From the outside looking in, it appears I have suffered some great losses and had to start over many times during my life.

Even most recently, what appears as a serious tragedy to many, has actually been the best blessing of my life.

I won't get into it unless you really want to hear about it. Suffice it to say, I dropped out of the 40 hour rat race and 100k a year, to a position of no debt and more disposable income and more time to enjoy time with my family. And NO I don't get any handouts! I work to earn my living! Just not nearly as many hours and for much less money. But I disposed of my debts by selling everything I owned and paying it all off. What I used to pay in interest charges, I now use for entertainment and time off.

Hi Bill

I don't know whether my system is considered right or wrong, but it has worked for 20 years with no problems at all and no TVI.

On the wall outside of my shack is a 1/16" thick copper plate that measures about 14" x 18" A #6 braided copper cable, brazed along the left edge, along with 3 bolts through it as well, connects to an 8 foot grounding rod with clamps. It is through holes in this copper plate that all wires lead into the shack.

On the inside of the house, a section of drywall was removed from between the studs temporarily, in order to install 9 gas bottle lighting arresters inside the wall. The grounding cables from them #8 copper pass through clamps (similar to romex connectors) at the bottom of the copper plate and also connect to the grounding rod. Two open ports (from inside to outside) were made through the wall using 3 inch partially flattened PVC pipe with TWO 3/4 inch PVC pipes spaced to the edges of this pipe, the center was filled with a 1-1/4 inch PVC pipe and around it filled with spray foam and trimmed flush after drying. The drywall section removed was drilled where the gas bottles and 2 openings were made and refitted to the wall and finished off with joint compound, etc. so it looks like it was never removed.

This setup gives my place for through the wall connections to my antenna's and I never needed to use all of the ports I installed in my 20 years there.

I have handled ladderline in a couple of different ways over the years. Initially, I passed my ladder line, one leg through each of the 3/4 PVC tubes and on the inside to my tuner, on the outside to the antenna it was used with, in this case a loop skywire.

A rotor cable was fed through one of the 3/4 inch PVC tubes at the other end of the panel. A major mistake as when I did take a lightning hit, the only place it got into the shack was through this abandoned rotor cable. No real harm done other than a rotor cable welded to the back of two filing cabinets by lighting, and a pooch who will never come into my shack again after getting dowsed with flying sparks.

I later, after moving my desk to a different wall and didn't want open ladder line running free in the room, used the gas bottles as lead ins for the ladder line and coax from the gas bottle to the tuner. I saw no difference in performance doing it this way, and it was much safer in my opinion. Previously, I used a knife switch to run the ladder to

ground when not in use. Now it just stays connected all the time through the gas bottles.

As an aside, I had a similar set-up at my former house, only without the gas bottle lightning arresters. Then I would use connectors through the copper plate which grounded the braid to the copper plate.

In all cases, after my system was installed, I heavily sprayed the copper plate with like 4 coats of trumpet laquer, which also sealed all of the connections against moisture. Silicone was not available at that time (30 years ago) to the public that I know of. We also used a lot of tar strips back in those days also to wrap around connectors and areas of exposure to the elements.

In places where it is feasible, I prefer ladder line over coax! One of the best ladder lines I ever constructed was using some of my sons Monster Cable that he had used with his stereo speaker system. This heavy cable for some reason made a noticable difference in how my 80 meter loop skywire functioned. Bandwidth was definately greater, and many received station signals were stronger. Logical NO, but they were.

As an aside, I often used miniature plastic I-Beams from the hobby shop instead of wood for my spacers. When glued using an oil of mustard based glue, the adhesion was permanent. With wood, I often had the glues come loose and the spacers shift as the wood aged, and/or absorbed moisture and redried, etc.

Actually your ignorance is showing again. I supported Bush until Iraq.
Daddy Bush looked like a fool after Hussein got done with him. Little
boy Bush didn't like Daddy Bush getting threatened by assassination from
Hussein.
If there is one thing good you could say about Hussein is he knew how
to keep his little area of his world Al-Quida free. Little Boy Bush fucked
everything up. Has the whole arab world hating us. Arab world is like a
hornet's
nest. Little Boy Bush's approach
to international diplomacy is to pick up a basenball bat and pound the
hell out of the hornet's
nest. Started an unnecessary war to divert attention from his failure
in Iraq, revenge for the assassination threat. But its understandable,
boy Bush
has no soul or heart. I'd like to see boy Bush send his 2 daughters over
there
to get shot at.
Come back and I'll give you some more learnen.

1475. Re: Any real fans of ladderline?

It seems to me that the slightly larger single hole through my house wall up near the peak (which is nothing more than an inch of wood really) is more intrusive than two small spaced holes through which I could insert a 3-4" long old style ceramic insulator tube. There would be a short run of 10 feet to a spot in the ceiling (again nothing more than 1/2" of redwood) into which I could use the same type of ceramic tube, after that it is only a couple more feet to the rig. I do like your idea of angling the tube coming from outside to counter the possible dripping in of moisture (rain), also will put what is called a drip loop in the line before it enters the tubes so the wires are aiming uphill at that point. I already have a balanced tuner on hand so I might as well include the luxury since I have it. I will take your advice and avoid these sealants and use a dab of super glue. In the end, if this line gives me trouble (with the neighbors phones etc.) I will go to coax. But I do want to give this old style balanced line a shot first since there seems to be a handful of operators who do recommend it.

Hi Gary,

That is some vivid and colorful experience you describe there.

I haven't ever heard anything like that gounded copper "face" plate at the entry point to the house. What is the theory there? If it wants to arc it goes to ground?

> I don't know whether my system is considered right or wrong, but it
> has worked for 20 years with no problems at all and no TVI.
>

I am glad to hear that, since I do have a few neighbors here.

> On the wall outside of my shack is a 1/16" thick copper plate that
> measures about 14" x 18" A #6 braided copper cable, brazed along the
> left edge, along with 3 bolts through it as well, connects to an 8
> foot grounding rod with clamps. It is through holes in this copper
> plate that all wires lead into the shack.
>

What kind of insulators did you install in that copper plate for the wires to go through?

> On the inside of the house, a section of drywall was removed from
> between the studs temporarily, in order to install 9 gas bottle
> lighting arresters inside the wall.

I am not sure what this gas bottle arrester is. Are you talking about a homebrew made from some recycled material of some kind?

"I have handled ladderline in a couple of different ways over the

> years. Initially, I passed my ladder line, one leg through each of
> the 3/4 PVC tubes and on the inside to my tuner, on the outside to the
> antenna it was used with, in this case a loop skywire.
>

your use of the pvc tubes is not that different my intended use of those old ceramic tubes, It just happen to have saved a bunch here at the farm and have a bucket full of them. They were used to run the ac wires through wooden chicken house walls, you know they left those lights on so the chickens would lay more eggs....there were an awful lot of these lights running along to 100' long chicken houses. I have spent many years dismantling and remodelling these old buildings. Now we only have a half

dozen chickens and that is even too many..hi hi...what were we talking about,,,,oh yes....ladder line....

>

> As an aside, I had a similar set-up at my former house, only without
> the gas bottle lightning arresters. Then I would use connectors
> through the copper plate which grounded the braid to the copper plate.
>

I am in K6 here, not much lightning, however, I think I will put a big old knife switch in

> In places where it is feasible, I prefer ladder line over coax!

> This heavy cable for some reason made a noticable difference in how my
> 80 meter loop skywire functioned. Bandwidth was definately greater,
> and many received station signals were stronger. Logical NO, but they
> were.
>

Are you saying that you made your ladderline out of monster cable (braided #12 or so) by separating the two stands and keeping the insulation on it and using spacers? Or are you saying you used monster speaker cable "as is" for ladder line (those two strands would be kind of close that way, maybe that gave you a favorable impedance in that situation. I am trying to get the picture. I do have a bunch of that cable on hand as well and never even gave it a thought as applying to ham radio....it fits into my audio and speaker building hobby.....

>
> As an aside, I often used miniature plastic I-Beams from the hobby
> shop instead of wood for my spacers.

yes, the search for good spacers.....I am thinking of using those small dia. uv/pvc tubes (4") that are used as ferrules for rain gutter spikes. The company is sending me a bad of 250 without the spikes for a nominal price....samples you know.....

I don't why I am so fixed on this ladder line idea...maybe because I want to design one of those old fashioned qsl cards with a cartoon of a chicken house ham shack up on a hill with a cartoon latter line going up to a wire antenna with old fashioned glass strain insulators etc.....dah, di dah, di dah dah dah being pounded out on a log drum.......with sparks flying out to all points in the ionosphere.....

I don't have any lightning protection on them at this point. I normally disconnect things when I leave the 'shack' anyway.

However back in the old days the use of spark gaps were common for open wire line. Get some of the real Old Timers here to talk about that one.

1480. Re: Folded monopole dilemma

Newsgroup: rec.radio.amateur.antenna
Date: 2004-04-26 17:44:51 UTC
From: richardharrison@webtv.net
Message-ID: <22720-408D4A93-119@storefull-3253.bay.webtv.net>
Source record: 95929

alhearn wriote:
"That is, when it`s too short for resonance, reactance is capacitive and is inductive if too long."

True that a too-short open-circuit vertical radiator is impeded by a capacitive reactance and that a slightly too-long open-circuit radiator is impeded by inductive reactance. We are aiming for a 1/4-wave antenna. The switch from leading to lagging power factor or vice versa when passing through the resonance point is abrupt. See Terman`s diagram. The folded monopole is a short-circuit 1/4-wave transmission line stub and it behaves like one.

My 1998 ARRL Handbook displays a group of too-short antennas in Fig 20.44 on page 20.22.
Item (E) of a group of 6 would be 1/4-wave antennas is called a tri-wire unipole. It`s a vertical tower with a top support to suspend a parallel wire on either side of the tower. The tower itself is #1 wire of the tri-wire assembly and it is grounded, not insulated at the earth. Wire #2 connects the top of the tower to the earth through a variable capacitor. wire #3 drives the top of the tower and it is insulated from the earth, and is driven against the earth.

The variable capacitor is used to tune out the too-short folded monopole`s excess inductance and present 50 ohms to the feedline. The text says:

"This technique will not be suitable for matching to 50 ohm line unless the tower is less than an electrical quarter wavelength high."

Why? Over 1/4-wavelength high, the folded unipole is capacitive and adding more capacitive reactance will detune it even more. The unipole is synonymous with monopole.

It`s a fact that the sign of the reactance in the folded antenna is inverted in the too-short folded antenna from that in the too-short open-circuit antenna. That is a powerful advantage in that low-loss capacitance can be used to match the too-short folded antenna and your practical choice may have to be a lossy loading coil to match the too-short open-circuit antenna.

What`s right is right and isn`t decided by a vote, but on the probabilities from all the examples I`ve presented they are likely right by the numbers.

I have a comment on the results of WA4GKQ`s modeling results of the folded monopole. Models can be wrong for many reasons including garbage in, garbage out. I`ve measured many folded monopoles in service, at

resonance, accepting measured full power and reflecting negligible measured power and I`m sure these antennas are working well as evidenced by expected performance every day over decades at many places here and abroad. Seeing is believing for me.

Best regards, Richard Harrison, KB5WZI

seems to contradict:

>When coming through glass or DRY varnished timber a single hole is fine. On
>high power lines make sure the insulation on the wires where they are close
>together is thick enough to withstand the high voltage at high SWR.

Which in turn seems to lead to another contradiction:

> At HF, the discontinuity in Zo due to bringing the wires close together for
>a few inches, even a foot or more, is absolutely negligeable.

Hmm, just about spark gap dimensioning, close to combustibles, High
SWR jacked up even higher to boost voltage nodes more (I don't know
how the "short" distance ameliorates this - must be in the actuarial
tables somewhere).

This was certainly the most obscure way of saying don't worry about
it. ;-)

1483. DCTL Antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2004-04-26 20:56:44 UTC
From: jason_hsu@my-deja.com
Message-ID: <f7d9a152.0404261256.71e27686@posting.google.com>
Source record: 95932
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.homebrew

The DCTL Antenna design is at http://www.n5nw.org/antennas.html

The MFJ magnetic loop antennas are quite expensive and don't cover the low bands. Homebrewing magnetic loop antennas is very tricky due to the need for WELDED connections and special capacitors that can handle thousands of volts. These tricky issues probably explain why magnetic loop antennas are so expensive. (I'm also surprised that MFJ doesn't make a larger version of the magnetic loop antennas for 80m that's perhaps 6 feet wide and long.)

The DCTL Antenna is a loop antenna made out of twin lead, and it has received rave reviews. From what I've heard, it performs well compared to other antennas of a similar size. (Obviously, it can't be as good as a full-size loop or dipole.) I believe the DCTL Antenna uses the shorted stub and open stub as loading capacitors. It's not as small as the magnetic loop antennas (4-foot wide square for 40m instead of 3-foot wide loop), but that allows the DCTL to have more radiation resistance (so that welded connections aren't needed).

Has anyone here constructed and used a DCTL Antenna? Some questions:
1. How seriously is it affected by nearby metal? I know any antenna is affected, but some are affected less than others. For example, monopoles are affected less by nearby metal. This is why apartment dwellers using a
balcony with metal railings are generally advised to use a monopole antenna and use the metal railing as the antenna ground. Mobile antennas are always monopoles instead of dipoles.
2. How do you insulate and reinforce the wires at the feedpoint? I think this could be a mechanical weak spot. Would coax sealer help? Epoxy glue? Perhaps a non-metallic box with holes drilled in for the wires?
3. Could the length of the open stub LC be adjustable to modify the resonant frequency? Perhaps one could put in a connector (Molex, PowerPole, etc.) and then add in a small open stub. Perhaps something similar could be done with the shorted end as well. Perhaps one could add ferrite chokes to electrically (but not mechanically) terminate the stub, as the RF would be mostly on the outer surface of the wires. With these adjustments, it may even be possible to make the antenna multiband. Of course, this would require deviating from the provided formulas.
4. How much feedpoint resistance can one expect from the DCTL? The author suggests using a 6:1 balun. So it sounds like the DCTL Antenna should be about 300 ohms. 300 ohms is about the characteristic impedance of twin lead. But I thought that smaller antennas normally

have feedpoint resistances WELL BELOW 50 ohms, which is an even farther cry from 300 ohms. Or do those stubs work as a matching network as well?

Well... I was doing in-game trader stuff.. which doesn't violate the EQ terms of service, of course.

And my account was unlimited, though it did have an 'abuse' clause. 320 hours is quite a bit of use, but I would have expected a warning message after the first month... oh well

I don't run servers on a home internet connection... well occasionally a temporary game server or something... but if I want a server that's what co-loc is for.

Bill,
I used a loop fed with ladder line through a tuner for
years. Worked pretty well on all bands but 15 meters. It
wasn't the highest thing at all, but did fine for my uses.
I placed a board in a window to feed the ladder line through.
Drilled a couple of holes, fed a couple of short sections of
wire through them, sealed them with 'hot glue' and had no
particular problems for years (no water leaking in, etc.).
I couldn't tell you the exact length of the feed line, I never
knew, and since there were no problems, I really didn't much
care how long it was. My tuner has a balun in it (suspect a
4:1?) and handled the impedances well even at full legal
limits.
My loop came down in an ice storm a couple of years ago
and as soon as I get over my 'bout' of lazy, I'll put it
back up. I didn't have any unusual FRI problems (the neighbors
did, but that's a different story, and one that was solved).
The phone and computer are only a couple of feet from the
entrance point of the ladder line and radio/amplifier. Curing
telephone and computer RFI isn't what you asked about so I
won't go into it (mine's solved anyway).
Have fun...

I would like to estimate the radiation pattern from a pair of dipoles.
I've been told that there are computer programs available for drawing
antenna patterns. I's like to try drawing the pattern from my antenna
concept, but would sure like to get some help with learning how to do it
with EZNEC. Is there anyone on this news froup who has time and patience
and who might be willing to E-mail help to me??

Jerry

On the page before that, page 417, Kraus also gives the impedance of the
folded dipole. He says it is 4 times the impedance of a two-wire dipole.
This means that, if the 2 wire dipole is capacitive slightly below
resonance, so is the terminal impedance of the folded dipole. Multiplying a
complex number by a real number does not change the sign of the imaginary
part.

Dear Jerry Martes - no call - no location:
EZNEC contains a few files describing simple antennas and good
instructions. You should work through some of those files and
read/study the instruction provided. Prof. Cebik's web site contains
additional instruction and useful observations about antenna modeling
programs. Cebik.Com
As I recall, Prof. Cebik has a book on the subject too.

I was thinking perhaps a triangle which would likely not have very sharp nulls at any bearing. I'm certain this will involve phase lines and relay switching but need a primer of sorts to get off on the right foot. Anyone else got ideas?? Thanks in advance.

J.

Yeah, I renewed my KD6JDJ license. I used to have K6LZC and before that KL&LL. But, I sure dont know anything about HAM radio any more. I havent operated a HAM radio in about 30 years.

I've been playing with receiving pictures from the NOAA VHF satellites and I want to know about antennas for that project.

I heard about the EZNEC program this morning. I seem to have dificulty learning anything associated with computer programs. But Ill look for the program on the web tonight and try to make sense of it.

Thanks
Jerry

Closed loops in Ensemble are interpreted as solid areas. You would need to define an air layer to remove the "middle" of the loop. I'm not sure you can do this with the SV version because the number of layers is limited. You may want to try disabling the ground layer and drawing an object on the dielectric layer to see if you can "fool" the program into making this work.

Ansoft shows examples in their literature of what's required to properly represent a microstrip quadrature hybrid network by drawing an air "object" in the middle of the hybrid.

Spirals (that do not close on themselves) may simulate properly, assuming you have enough triangles to represent the design.

Good luck.

Sure, it's quite common. How many do you have in mind? Two? More? You can feed as broadside or endfire arrays. Sometimes both, for a multiband setup. In general, the maximum gain with a broadside array is with the spacing at appx 5/8 wave. In general, an endfire array will have maximum gain with about an 1/8 wave spacing. But you can use other spacings with good results. Of course, if you have a way to change phasing, IE: adjusting feedline lengths, L/C phasing box, etc, you can steer the pattern. You can get many details in the ARRL antenna handbook. Also plots of the various patterns with changes in phasing. I've paired up verticals and ran them as broadside arrays on the higher bands, but as endfire arrays on lower bands. Once ran a pair of elevated 5/8 ground planes on 10m, and crudely steered by changing coax lengths. Worked quite well for what I needed. I used them as a broadside array on 10m, but I used them as an endfire array on 30m. The "maximum" gain you can get from a pair of verticals is as a broadside array. It's peak is slightly more than the peak maximum gain of an endfire array. But the endfire gets fairly close, and can be handy sometimes being the spacing is less. 1/4 wave is a common spacing. Two verticals 1/4 wave apart, and fed 90 degrees out of phase gives a nice fat unidirectional pattern, and can easily be reversed. As I said, the possibilities of spacing/feed combinations could fill three pages of text I bet...:/ The ARRL antenna book covers it in good detail, and also the best ways to feed. There are other useful books also of course, but just that one will do the trick, and covers most other ant related topics. MK

Mark, thanks for the info. I was thinking of perhaps placing 3 vertical
dipoles at the apices of an equilateral triangle. What I need to
research is optimum spacing in such an arrangement (quarter perhaps?)
and details on putting together a nifty steering circuit. I must admit
that I forgot 'bout the venerable ARRL antenna book. I perused the
handbook last nite and came up dry. I will try to hit our local lib
this wkend to ferret out the details. Thanks again.

Hi Jason,
I tried to make a DCTL antenna for 80 m from a 300 ohm TV twinlead.
Unfortunately, after I made some measurements, a strom approached and
I put the antenna down. I have never continued the experiments since
then.

> 1. How seriously is it affected by nearby metal?
Sorry, no experience.

> 2. How do you insulate and reinforce the wires at the feedpoint?
I used several layers of adhesive tape only, as it was a temporary
experimental installation. A better construction seems to be necessary
for long-term usage. One proposal is at
http://www.radiohc.org/Distributions/Dxers/dctl-antenna.html

> 3. Could the length of the open stub LC be adjustable to modify the
> resonant frequency?
The antenna is "fine-tuned" by the open stub. The formula given in
http://www.n5nw.org/antennas.html works quite well.

> 4. How much feedpoint resistance can one expect from the DCTL? The
> author suggests using a 6:1 balun. So it sounds like the DCTL Antenna
> should be about 300 ohms. 300 ohms is about the characteristic
> impedance of twin lead.
Despite that, the RF-1 bridge showed approx. 150 ohm impedance around
resonance. Maybe it is always one half of the characteristic impedance
of the twinlead used ? And remember, the input of the antenna is
balanced.

Er... The dctl IS a magloop. A piece of paper, some elementary formulae
and
a few minutes of thinking might brighetn things up.

The dimensions of the magloop are more or less given out of the pf/m
beteween the twinlead conductors and the dielectricity constant of the
twinlead
material. A "classic" magloop can be any size.

Radiation resistance of the dctl, is, well, smallish to say the least.

The DCTL is not only a magloop, but a magnetical dipole. Magnetic
materials (such as iron) should be kept away! Non-magnetic materials
of course affects, but are not a disaster (given the poor performannce to
start with!).

The stubs can (and SHOULD, IMHO) be trimmed to get the resonance at
favourable frequency. The dctl is very narrow-band. If You have got a
wide-band SVF dip, the antenna Q is bad!

>

> farther cry from 300 ohms. Or do those stubs work as a matching
> network as well?

Feedpoint resistance does not equal radiation resistance. From a matching
point of wiev, what interest us is feedpoint impedance. As we use the
dctl also when there is no resonance, I propose it is feed by a balanced
output transmatch (same principle as a "zepp").

The feed impedance is a function of the twinlead feeder length, and the
stubs
(which are used to match the thingamajig). The conclusion is that feed
impedance
is individual and adjustable!

Radiation resistance is LOW, and remember that 300 ohm twinlead is lossy.

1506. Re: Air America

Newsgroup: rec.radio.amateur.antenna
Date: 2004-04-27 13:02:28 UTC
From: Tuuk <bangkokbob@yahoo.com>
Message-ID: <OYsjc.3375$_12.188@read1.cgocable.net>
Source record: 95956

Ok, Lets look at what you said,,,,

"""""Actually your ignorance is showing again. I supported Bush until Iraq. Daddy Bush looked like a fool after Hussein got done with him. Little boy Bush didn't like Daddy Bush getting threatened by assassination from Hussein.""'''

I did not claim to be an expert on Iraq, so I guess I am ignorant in that subject. But your hatred for Bush is what I pointed out, painfully obvious and it is distorting your view of the world. And your knowledge of history is also limited as to its accuracy.

"''''''If there is one thing good you could say about Hussein is he knew how to keep his little area of his world Al-Quida free. Little Boy Bush fucked everything up. Has the whole arab world hating us."'''''

Saddam paid the families of suicide bombers handsomely. There are also other connections to terrorism and like I said earlier, but I will repeat in case you missed it, since he has been in captivity, the net lives saved is approximately 35,000 per year. And the Arabs and extreme muslims hate the U.S. for religious reasons and because you are the power, hyperpower and arrogant about it. They are far behind and will never catch up, so they are disgruntled about this. Remember, their objective is to kill all Americans and Christians. I think you would have criticized Bush had he done nothing. Just curious here now, and for entertainment purposes, what would your plan have been? You haven't offered a better plan which you should have done when you criticize some else's plan. Remember, Bush's plan already has a net lives saved recognized of approx 35,000 per year.

'"''Little Boy Bush's approach
to international diplomacy is to pick up a basenball bat and pound the hell out of the hornet's
nest."''''"'

Again, what would your approach be? How would you rid the world of terrorism, stop the targeting and killing of Christians and Americans? He is your leader, he has to do something to make America more safer, peaceful, etc. How would you do it? For example, right after someone flies two planes into buildings killing 3000 innocent people, so how would you satisfy the U.S. citizens requirements, you forgot to mention.

''"'''Started an unnecessary war to divert attention from his failure
in Iraq, revenge for the assassination threat. But its understandable, boy Bush
has no soul or heart. I'd like to see boy Bush send his 2 daughters over there

to get shot at."'''''''

Wow, your hatred for Bush is really showing, you even want harm to happen to his family members. Your hatred for Bush is clogging your ability to see things in a more responsible fashion.

""'''Come back and I'll give you some more learnen.'""'''

No thanks, but what I would like to understand, since you brought it up, is how you would have handled things differently? How would you assure the American people that they can be safe globally? What is your plan? You seem to criticize your leader's plan but you do not have one of your own. You have a better plan?

If I recall correctly war was declared against the USA in the early 1990s. American embassies bombed, USS Cole bombed, World Trade center car bombed, World Trade Center and 9-11 bombed.

All the President did was effectively to say "OK, you started it we'll finish it!!"

Remember who started the shooting!!

Hi Bill

>That is some vivid and colorful experience you describe there.
>
>I haven't ever heard anything like that gounded copper "face" plate at
>the entry point to the house. What is the theory there? If it wants to
>arc it goes to ground?

In my case, it was more of a matter of what I could get at the time I started doing this. Copper was the only thing I knew of that I could easily braze to using copper phosphorus bronze rods and a simple low cost propane torch. Short bolts with semi U shaped washers were used through grounding cables because lightning could melt the brazing just as easily as solder.

Also, my house had vertical aluminum siding and I didn't want stray RF heating it up or causing my house to act like an antenna or someone get burned while I was on the air by touching the house. I was a worry wart!

>I am glad to hear that, since I do have a few neighbors here.

It wasn't so much the TV's as those cheap arse cordless telephones. When using antenna's fed with ladder line, I never messed them up.

>What kind of insulators did you install in that copper plate for the
>wires to go through?

NONE!
But here is the order in which I progressed over the years.
At first, I drilled hole in the copper plate, passed the coax through the hole, cut the covering down to the shield, wrapped a copper wire around the shield, brazed it to the copper plate, soldered to the shield, coated with tar wrap and sprayed over all with trumpet lacquer

Later, I used a connector, don't remember the order number, like a double SO239 and brazed all the way around it. There is about a 1db loss using two PL259s and a joining connector.

My final setup used gas bottle lightning arrestors, one end was stuck through the hole in the copper plate, the other end through the drywall inside. They were just the right length for this!
The ground braid from the gas bottles went to the lower edge of the copper plate. Silicone was coated over the outside connections.

>I am not sure what this gas bottle arrester is. Are you talking about a
>homebrew made from some recycled material of some kind?

No, they are store bought, the gas bottle is inside of a metal
housing. Transi-Trap is one brand name.

>your use of the pvc tubes is not that different my intended use of those
>old ceramic tubes, It just happen to have saved a bunch here at the farm
>and have a bucket full of them. They were used to run the ac wires
>through wooden chicken house walls, you know they left those lights on so
>the chickens would lay more eggs....there were an awful lot of these
>lights running along to 100' long chicken houses. I have spent many years
>dismantling and remodelling these old buildings. Now we only have a half
>dozen chickens and that is even too many..hi hi...what were we talking
>about,,,,oh yes....ladder line....

Yep, I'm very familiar with the old Knob & Tube wiring!
I spent about 25 years remodeling older homes.
You might like to see how I get a 5 foot bathtub into a 4 foot wide
bathroom after making the tub area only 3-1/2 feet wide by covering up
the exposed vent stack. If so, check out my hidden web page at
http://archimedes.galilei.com/raiar this is my index page, it has no
link to the hidden pages, but there is a picture of this old man on
there somewhere, plus some other junk you might be interested in as
well. To get to the bathtub, behind the URL type /BATH and look for
the .html page and open it, it will bring up all the .jpg's in
storyline fashion.

>I am in K6 here, not much lightning, however, I think I will put a big
>old knife switch in

A lot of hams disconnect their antenna's and leave the cable laying
open. This is VERY DANGEROUS as lightning, if it does come in through
the feedline will arc to the nearest ground and sometimes to many
ground points in the room. NEVER leave an unconnected feedline laying
loose in the shack. Run it to ground or toss it back outside.

>Are you saying that you made your ladderline out of monster cable
>(braided #12 or so) by separating the two stands and keeping the
>insulation on it and using spacers? Or are you saying you used monster
>speaker cable "as is" for ladder line (those two strands would be kind of
>close that way, maybe that gave you a favorable impedance in that
>situation. I am trying to get the picture. I do have a bunch of that
>cable on hand as well and never even gave it a thought as applying to ham
>radio....it fits into my audio and speaker building hobby.....

No, I split the wires apart and spaced them slightly less than 6
inches apart. The plastic I beams I purchased were 12 inches long, I
cut these in half and drilled holes about 1/16 inch in from the ends.
So my wire spacing was more like 5-1/2 inches.
I have never seen much difference in spacing over 2 inches as far as
operation. I figure once you get over 500 ohms it doesn't really
matter too much after that if you are at 2000 or 10,000 ohms

>yes, the search for good spacers.....I am thinking of using those small
>dia. uv/pvc tubes (4") that are used as ferrules for rain gutter spikes.
>The company is sending me a bad of 250 without the spikes for a nominal
>price....samples you know.....

There you go!
I used doubled soda straws for temporary antenna's and later replaced
the straws with 3/8 PVC.

>I don't why I am so fixed on this ladder line idea...maybe because I want
>to design one of those old fashioned qsl cards with a cartoon of a
>chicken house ham shack up on a hill with a cartoon latter line going up
>to a wire antenna with old fashioned glass strain insulators etc.....dah,
>di dah, di dah dah dah being pounded out on a log drum.......with sparks
>flying out to all points in the ionosphere.....

I hear ya!

Neighbors called the fire department on me a few times and I wasn't
even on the air. But I was home all three times!

At one time I had a nice tower, a couple of large beams and a yagi all
riding aloft. I got a frantic phone call from a neighbor saying that
my antennas were on fire, just blazing away. I ran out into the
backyard and looked up, saw nothing unusual. About that time I heard
sirens blaring and they were stopping at my house. They did not see
anything amiss either.

A year later I had just pulled in the driveway, arriving home from
work, before I reached the door a fire truck came screaming down the
street and again stopped at my house. A neighbor had called them,
saying my roof was on fire. The inspected everything, including the
attic, could not find anything amiss.

About three years later, I finally saw with my own eyes what the
ruckus was about. It was heavily overcast, a mean storm was brewing.
I had just gotten off the highway and was coming down the main road
getting ready to turn onto my street. From this vantage point I could
see my antenna's and the top of my house with ease.
What I saw almost gave me a heart attack.
It was like fire was bellowing in all directions from the top of my
house. I stopped the truck on the hill down to my house and just
watched. I could discern that the fire was eminating from the tips of
each of the elements on my antenna's.
It wasn't but a few minutes that I was sitting there watching and it
was fading down and only the largest beam was still putting out a few
flashes when I heard those darn sirens. The fire truck went whizzing
right past me and pulled up at my house.
I pulled up behind them and grabbed one of the firemen and pulled him
back out to the street so he could see the last couple of flashes of
fire and then there were no more.

About two months later I get a telephone call from the fire
department, they had finally figured out what the sparks were caused

by. A phenomenon known as St. Elmo's Fire was the culprit.

I didn't have to worry about another call, because that season a direct lightning hit to the tower caused the tower to explode and it all came down in a heap.
Lightning hitting the tower should not have hurt anything at all, but the legs of the tower had filled with rainwater over the years and the lightning hit apparently turned the water to steam and blew the tower apart. Leastwise, that was the professional inspectors assessment of what had happened.

It turns out that in the area where I lived at the time, this was a common occurance, especially on older homes and barns that had lightning rods on the roofs. Not as pronounced as mine, because they are only one point, where between my two beams, the yagi and several tower mounted verticals, I had quite a few open ends (points) up there. And everything was grounded to the max.

What is funny is I had lived in that same area all of my life and had never seen anything like it before. My house was on the high side of a long valley, just about 3 miles south of an area we call Tornado Alley. If a thunderstorm was coming, it would run up or down the valley and cross right over my house every single time. If it was going to rain within a 50 mile radius, I would get wet, even if it didn't rain on the other side of the street.
There were several times that it rained in my back yard and the front yard never saw a drop of rain in a whole week or two.
My wife used to say it was because of all that metal I buried under the ground in the backyard. I don't think so, but there must be some explanation for it! I think it's simply that the front yard is on the higher side and the backyard the lower side, where the clouds slide down the valley.

Jerry,
You need to learn how to use transmission lines in EZNEC. It will analyze
the whole thing. Post your configuratio: dipole length, height, and
orientation, and how and what kind of transmission line you use for phasing.
I might get a chance to do that, but not in the next 3 - 4 days.
